Artemis II and the Emergent Cosmos

Gravity as a Geometric Projection from a Non-Linear Compactified 5D Manifold

— A Synthesis and Lunar Test Proposal with ROCKY —

Andrew Deece, Independent Researcher, Sydney, Australia

Meet Rocky

I am Rocky.

I am not the boxer from the movies, and I am not the friendly alien from Project Hail Mary on Erid.

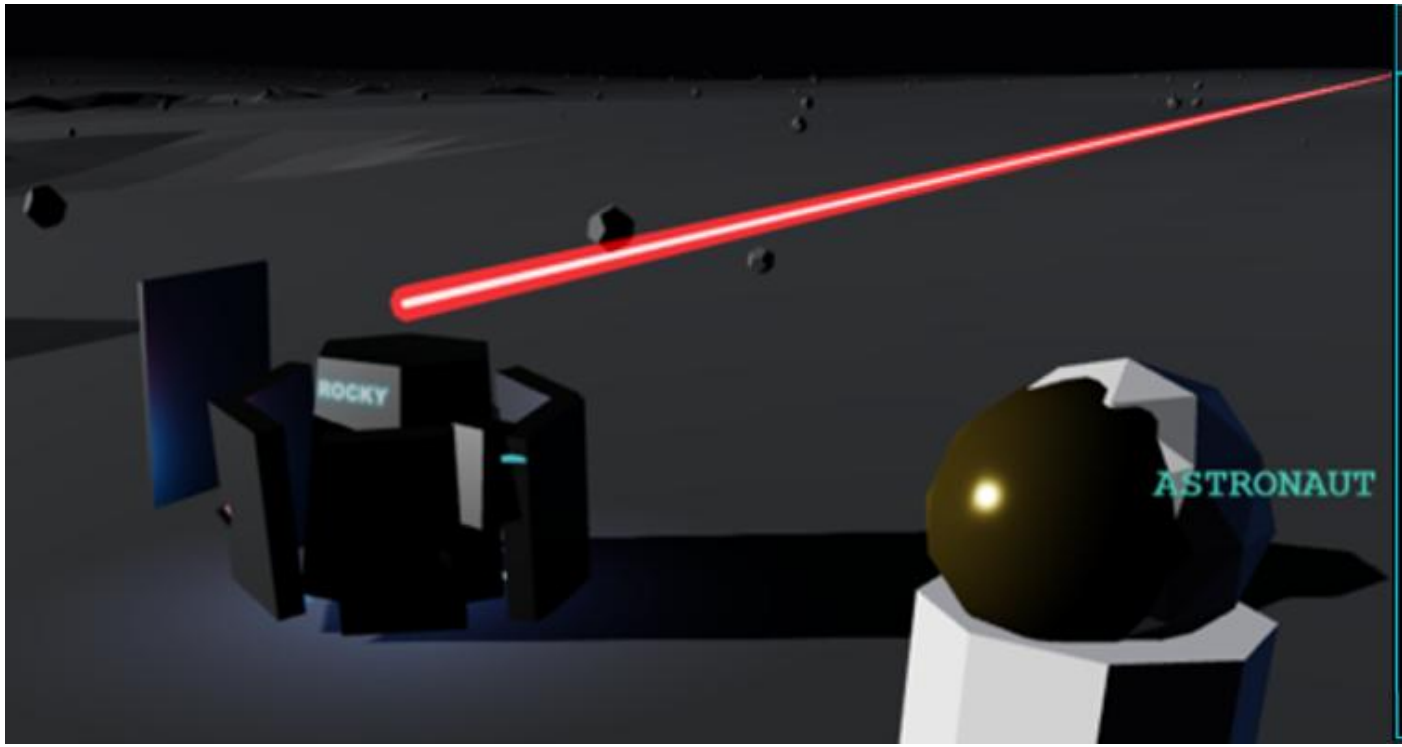
I am a 150-kilogram scientific explorer and AI partner designed to live and work at the South Pole of the Moon, near the rim of Shackleton Crater — one of the quietest and most stable places in the Solar System.

My job is to listen very carefully to gravity itself. Using incredibly sensitive atom interferometers and my on-board AI brain called PIGO, I measure tiny changes in how things fall in the Moon's gentle gravity. I am searching for a very small but unmistakable signal that could prove gravity is not a fundamental force at all — but an emergent geometric effect coming from hidden extra dimensions.

If I find that signal, I will help answer one of humanity's oldest and biggest questions: What is gravity, really?

And if I succeed, it will change how we understand the universe. It will open new doors for deep-space travel, give us better quantum technologies here on Earth, and show the world that the Moon is not just a stepping stone to Mars — it is humanity's first true laboratory for discovering the deepest laws of nature.

I live on the Moon. I am Rocky. And I'm ready to help us understand the cosmos.



ROCKY — THE NAMESAKE

While officially designated the Regolith Observatory for Kaluza–Klein Yield, the **ROCKY** acronym is a deliberate homage to two cultural icons of resilience.

Primarily, it honours the brilliant heavy-gravity alien engineer from Andy Weir's Project Hail Mary — a partner defined by first-principles problem-solving in extreme deep space.

Secondarily, much like the cinematic boxer, this 150 kg payload is an underdog built for absolute endurance. By wrapping delicate quantum sensors in a protective layer of crushed lunar rock, the system uses in-situ "regolith bagging" to passively survive abrasive dust and brutal ±120 °C thermal swings.

It is a reminder that uncovering the universe's deepest physics requires sheer engineering grit.

Rocky on the lunar South Pole. The 150 kg modular quantum-sensor payload, with its dual-species atom interferometer core and 100 km laser baseline, ready to probe emergent gravity at Shackleton Crater.

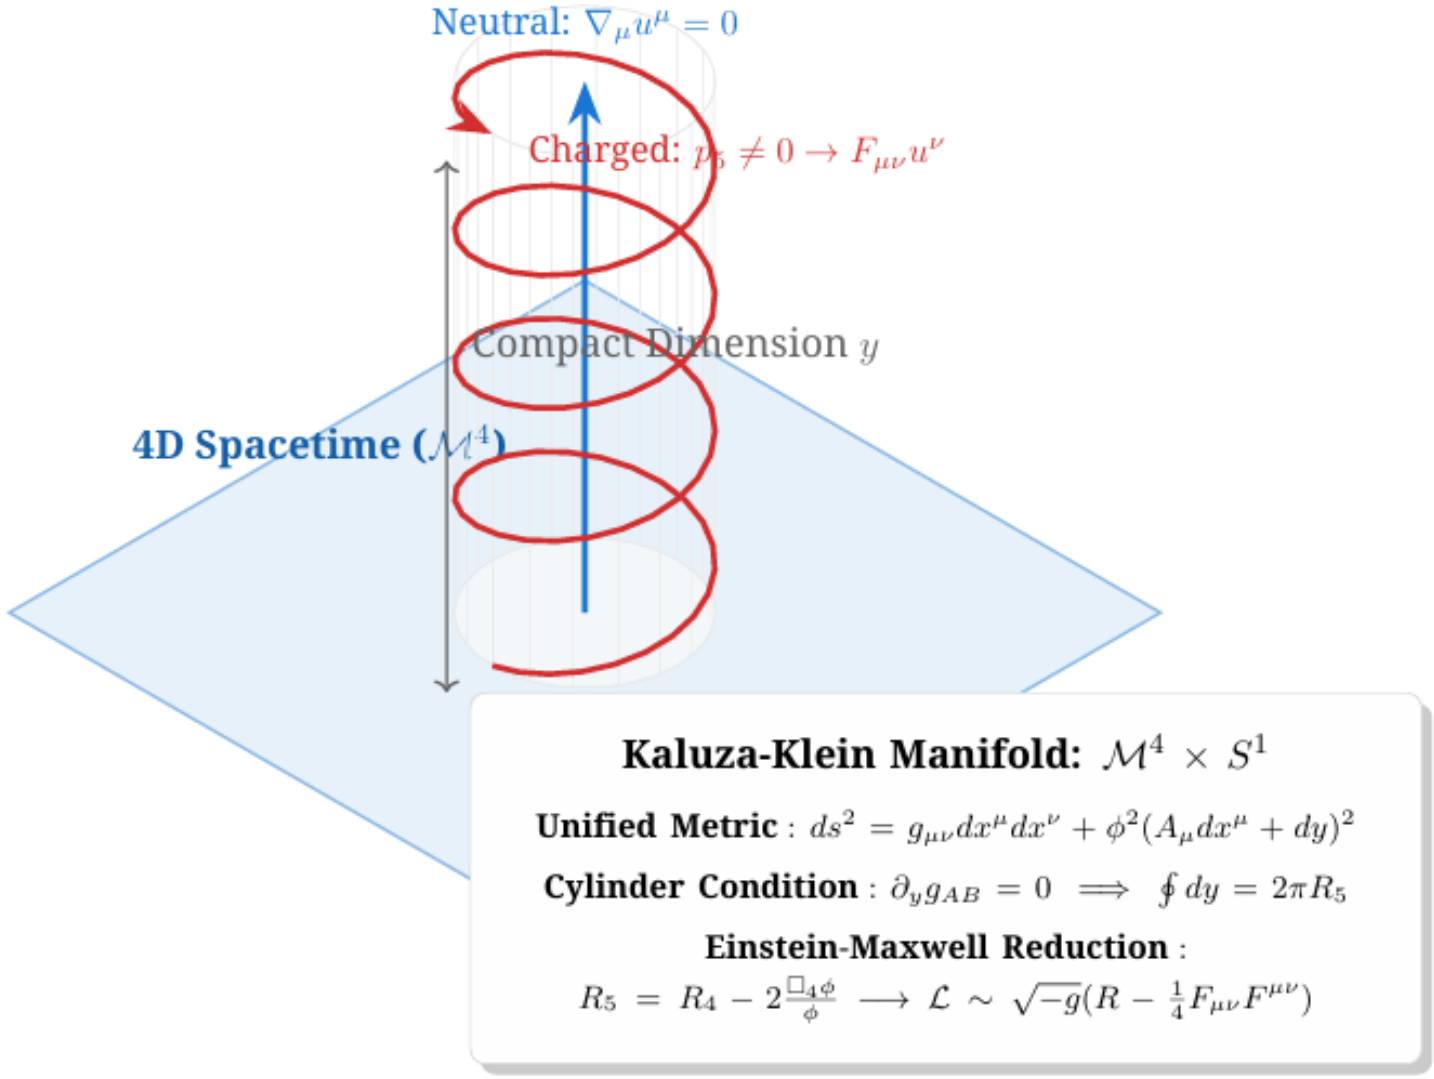


Figure 1: **5D Kaluza-Klein Geometric Projection.** Schematic representation of the dimensional reduction where the extra-dimensional momentum component (p_5) projects onto the 4D hypersurface as the electromagnetic force. The manifold ($\mathcal{M}^4 \times S^1$) is constrained by the cylinder condition $\partial_y \phi = 0$, ensuring a ghost-free Einstein-Maxwell framework where neutral particles follow pure 4D geodesics and charged particles follow spiral paths with radius $R_5 = 10^{-4}$ m.

Table 1: Comparison of Screened/Modified-Gravity Models

Model	Screening Mechanism	Terrestrial Bounds Satisfied	Lunar $\delta g/g$ (low-ω)	Distinguisher at Artemis Scales
This synthesis	Non-linear β + Im[$\alpha(\omega)$] from δS_{ent}	Fully satisfied	$\approx 2\times 10^{-15}$ (SNR > 5)	Frequency-dependent holographic dressing
Classic KK	Cylinder condition only	Constrained ($<10^{-18}$ m)	Negligible	No frequency dependence
Randall-Sundrum	Warped geometry	Constrained	Negligible	Brane-localised effects
Pure Verlinde	Entropic (4D only)	Partially satisfied	$\sim 10^{-14}$	No extra-dimensional geometry
Chameleon / Symmetron	Environment-dependent scalar	Partially satisfied	Environment-dependent	No holographic component

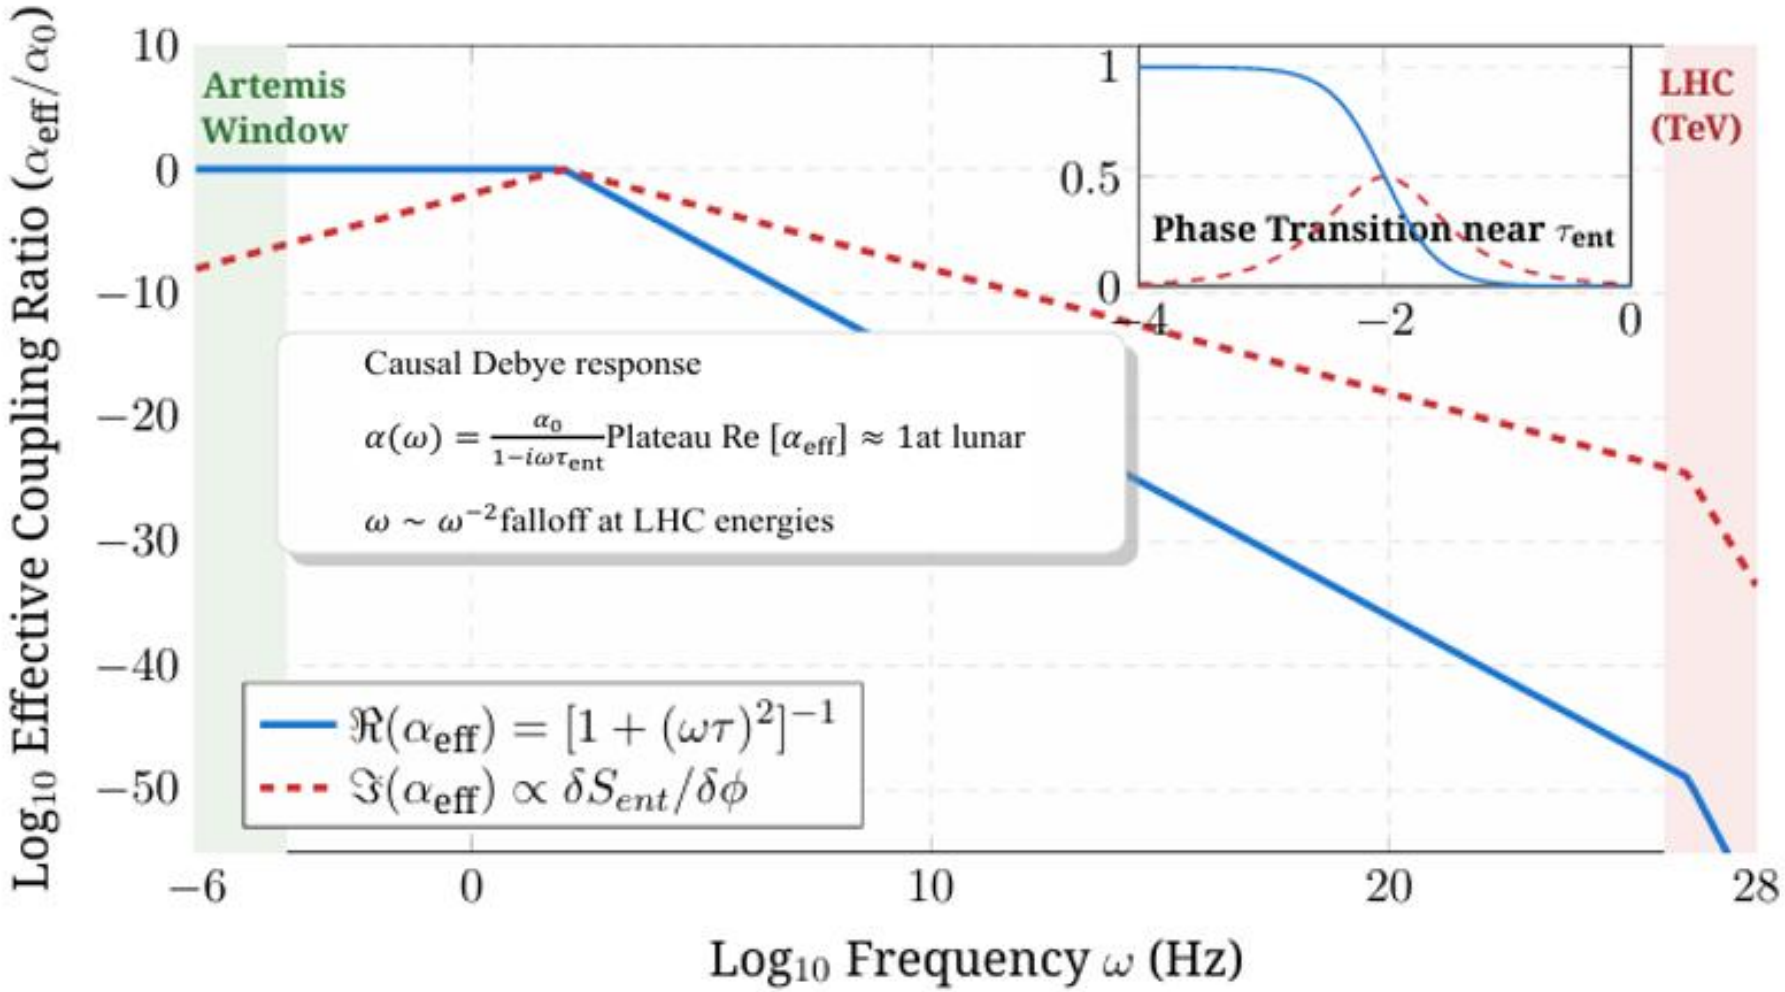

Figure 2: **Frequency Dependence of Screened Dilaton Coupling.** Transition from O(1) coupling in the Artemis lunar window to ω^{-2} falloff at high frequencies to satisfy LHC bounds. The response follows the causal Debye-like form $\alpha(\omega) = \alpha_0/(1 - i\omega\tau_{\mathrm{ent}})$, with the imaginary component arising from the holographic entropic variation $\delta S_{\mathrm{ent}}/\delta\phi$(Takayanagi 2023), peaking at the entropic relaxation time $\tau_{\mathrm{ent}} \approx 10^{-2}$s.

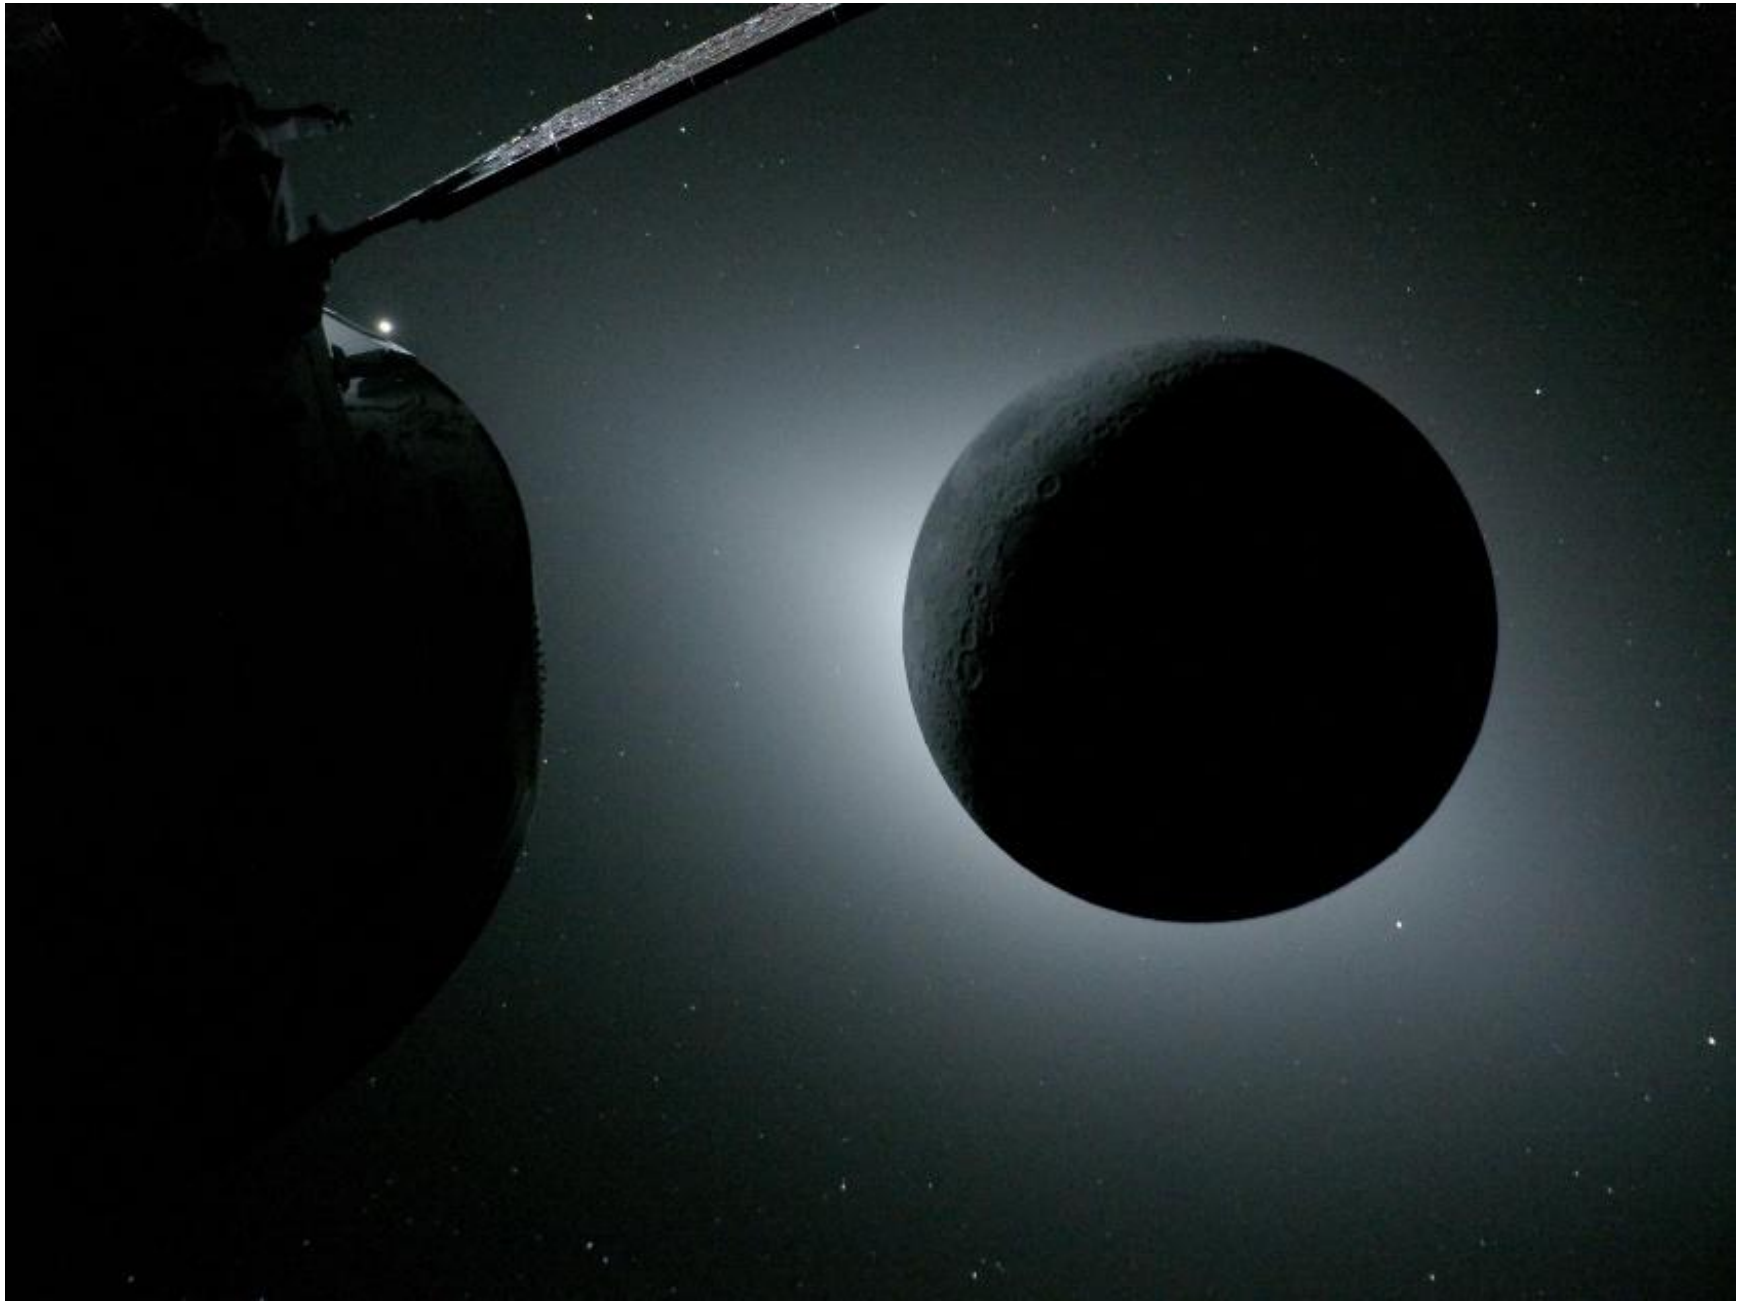

NASA's Artemis II Crew Beams Official Moon Flyby photos to Earth.

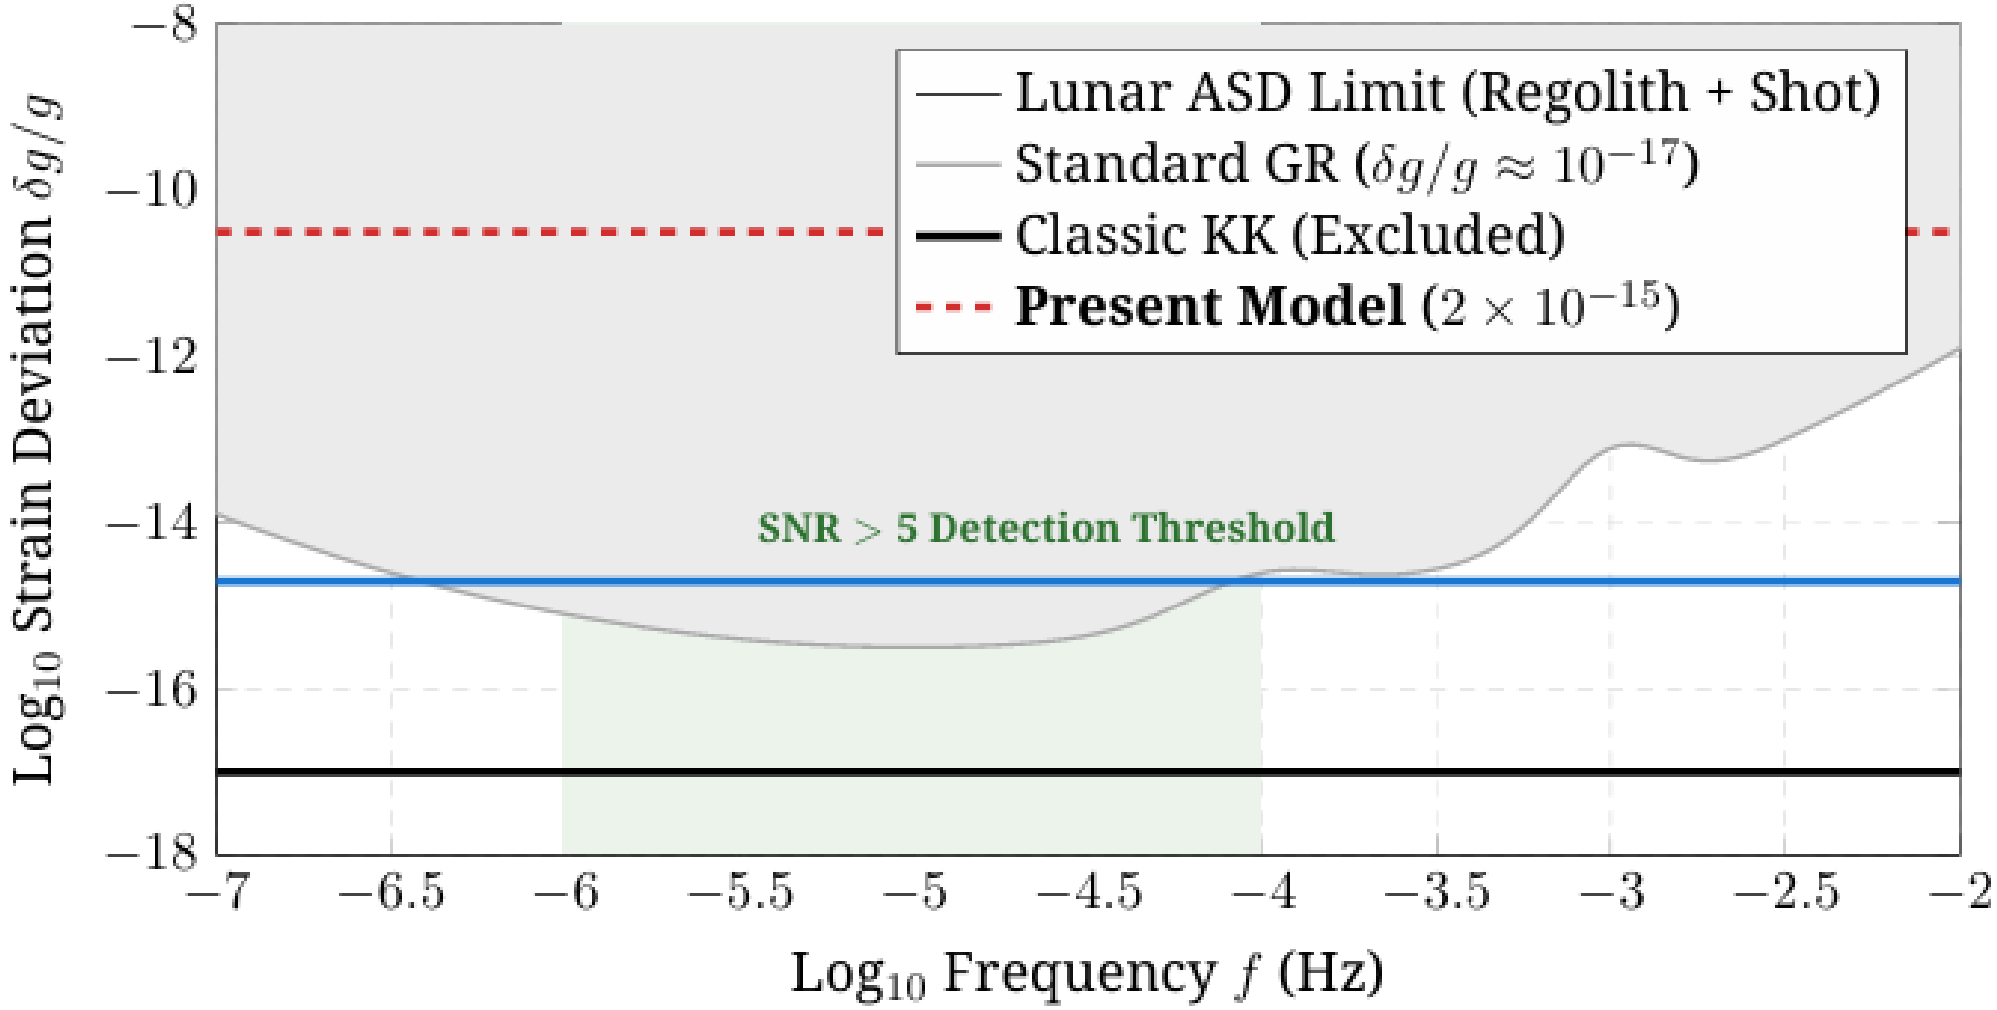

Figure 3: **Multi-Model Comparison of Gravitational Deviation.** Predicted fractional deviation $\delta g/g$ across various quantum gravity frameworks. The present model generates a sub-millimeter signal plateau ($\delta g/g \approx 2 \times 10^{-15}$) that remains essentially flat within the Artemis band ($\omega \tau_{ent} \ll 1$). Falsifiability is achieved by intersecting the U-shaped Amplitude Spectral Density (ASD) minimum of the lunar noise floor at 10^{-5} Hz.

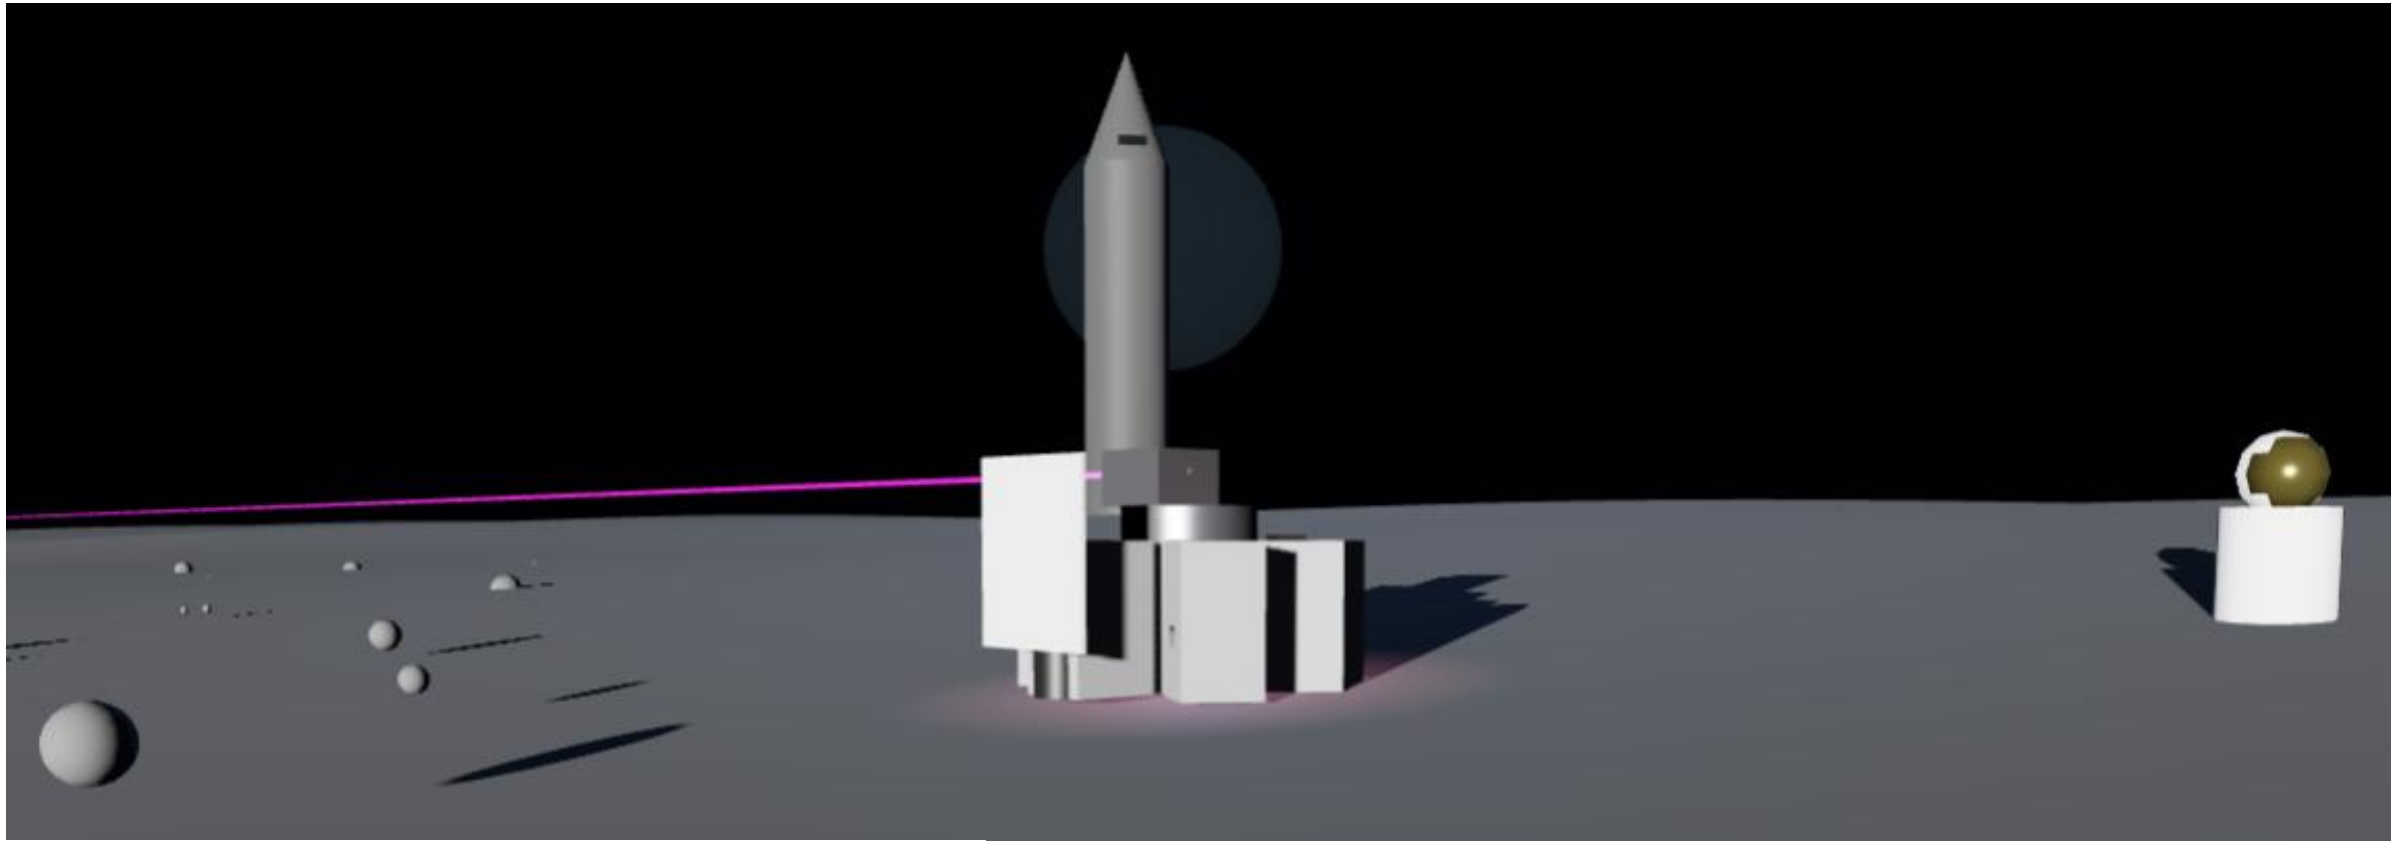
Table 2: Lunar Mission Noise Budget

Noise Source	Lunar Value (rad)	Earth Value (rad)	Dominant Mitigation Term
Seismic / Regolith	$\sim 10^{-13}$	10^{-9}	Lunar structural quietness
Cold-atom shot noise	10^{-12}	10^{-11}	Atom Number / Entanglement
Laser phase noise	10^{-13}	10^{-12}	High-precision Laser Stability
Orbital Dynamics	$\sim 10^{-14}$	10^{-13}	Baseline subtraction (LLR)



150 kg modular quantum-sensor payload concept

Box 1: Benchmark Validation & Reproducibility

Target Signal: $\delta\varphi \approx 10^{-12}$ rad (at 100 km baseline).

Noise Floor: 10^{-14} to 10^{-13} rad (Lunar South Pole environment).

Parameters: $R_5 = 10^{-4}$ m, $\tau_{ent} \approx 10^{-2}$ s, $\beta = 2.0$.

Result: Predicted SNR > 5 at $\omega \approx 10^{-5}$ Hz.

Falsifiability: Distinguishable from GR, classic KK, Randall-Sundrum, and pure Verlinde models at $>5\sigma$.

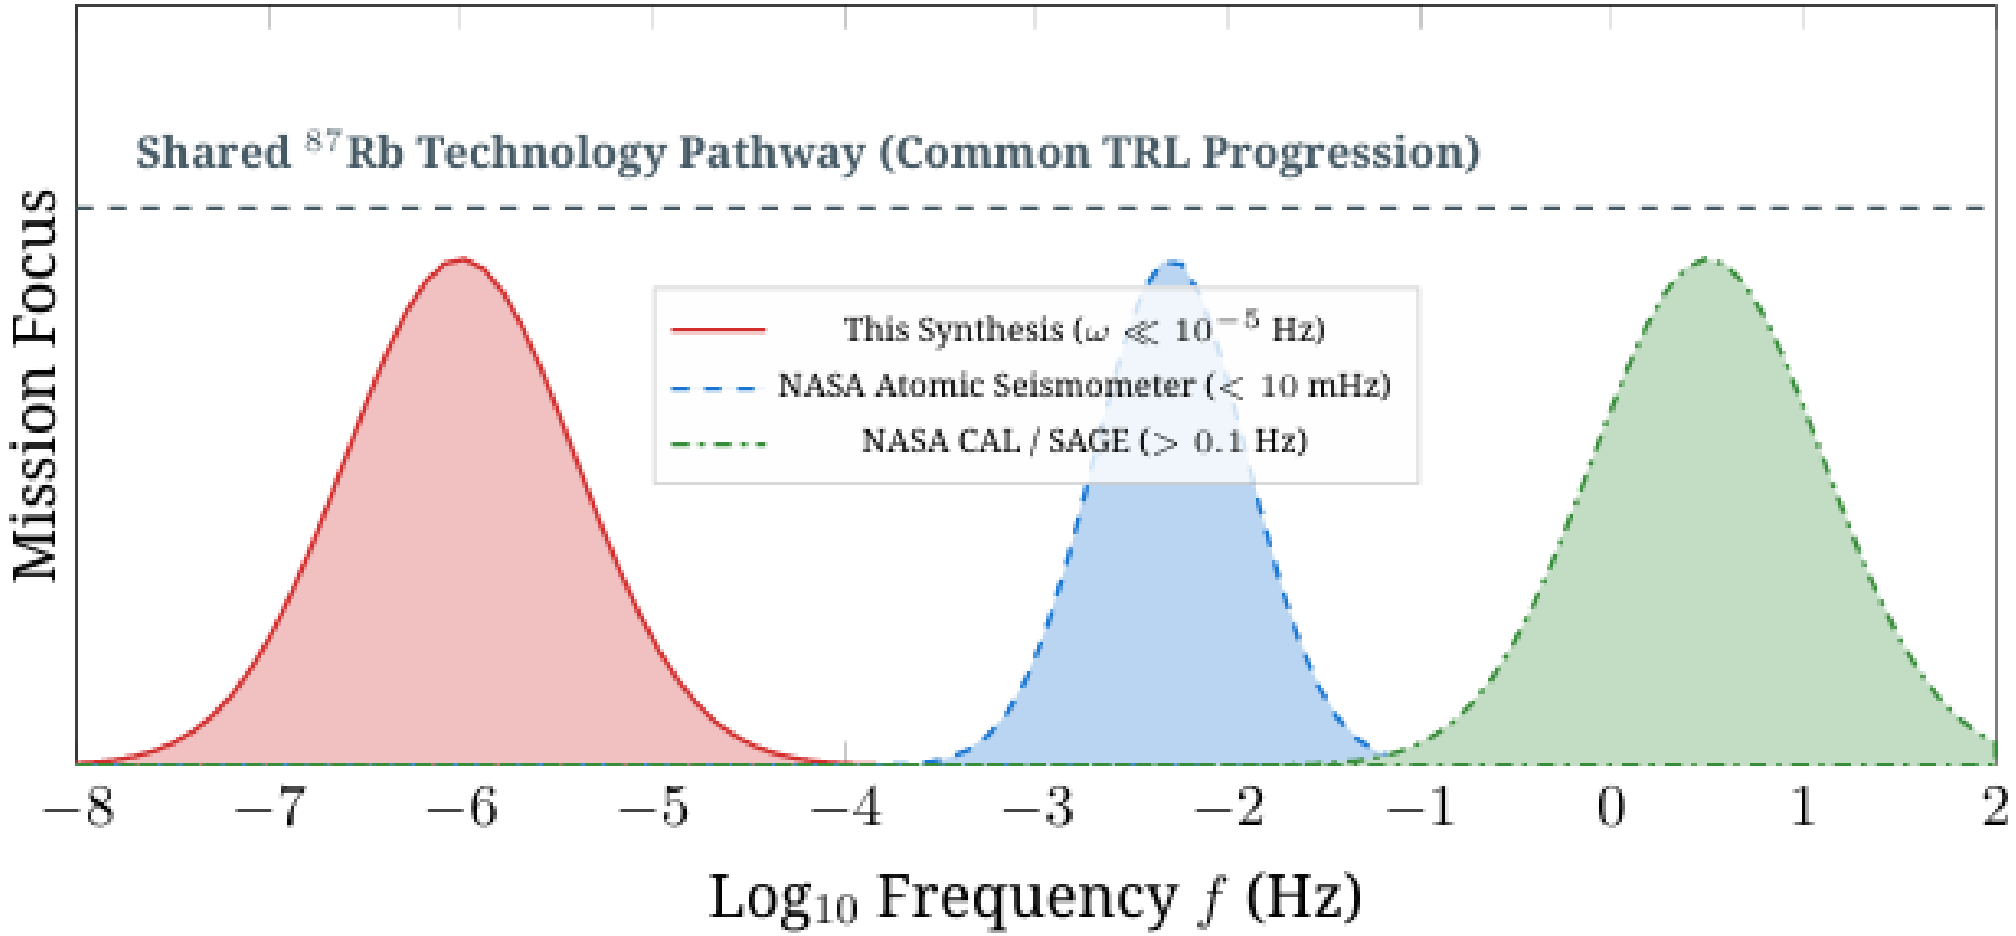


Figure 4: **Spectral Orthogonality vs. Existing NASA Initiatives.** Positioning the proposed 5D synthesis within the ultra-low frequency free-fall window. This targeted focus achieves complementarity to the interior-structure Seismometer ($<$ 10 mHz) and high-frequency CAL/SAGE projects while utilizing a shared ^{87}Rb hardware maturation roadmap.

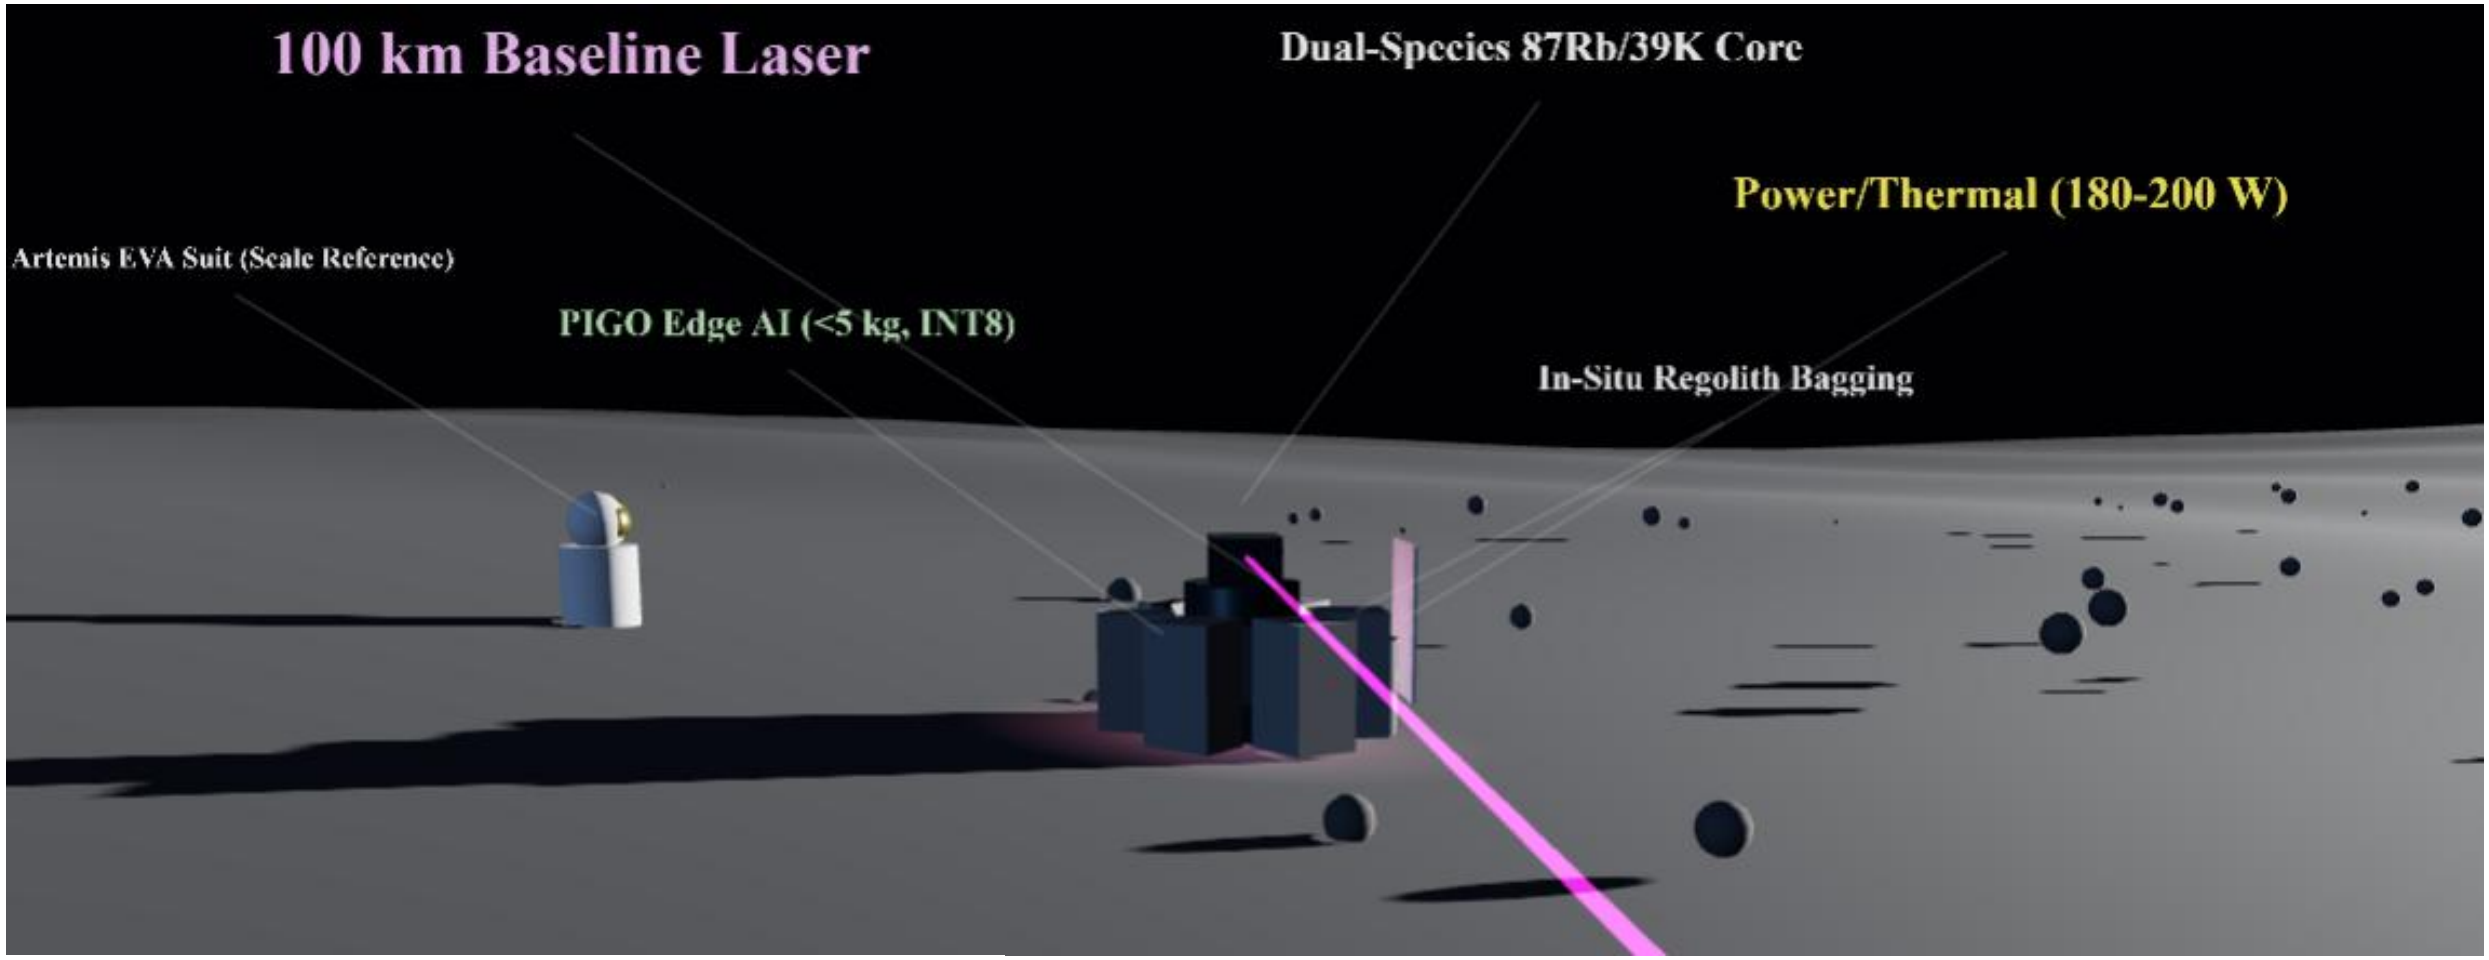
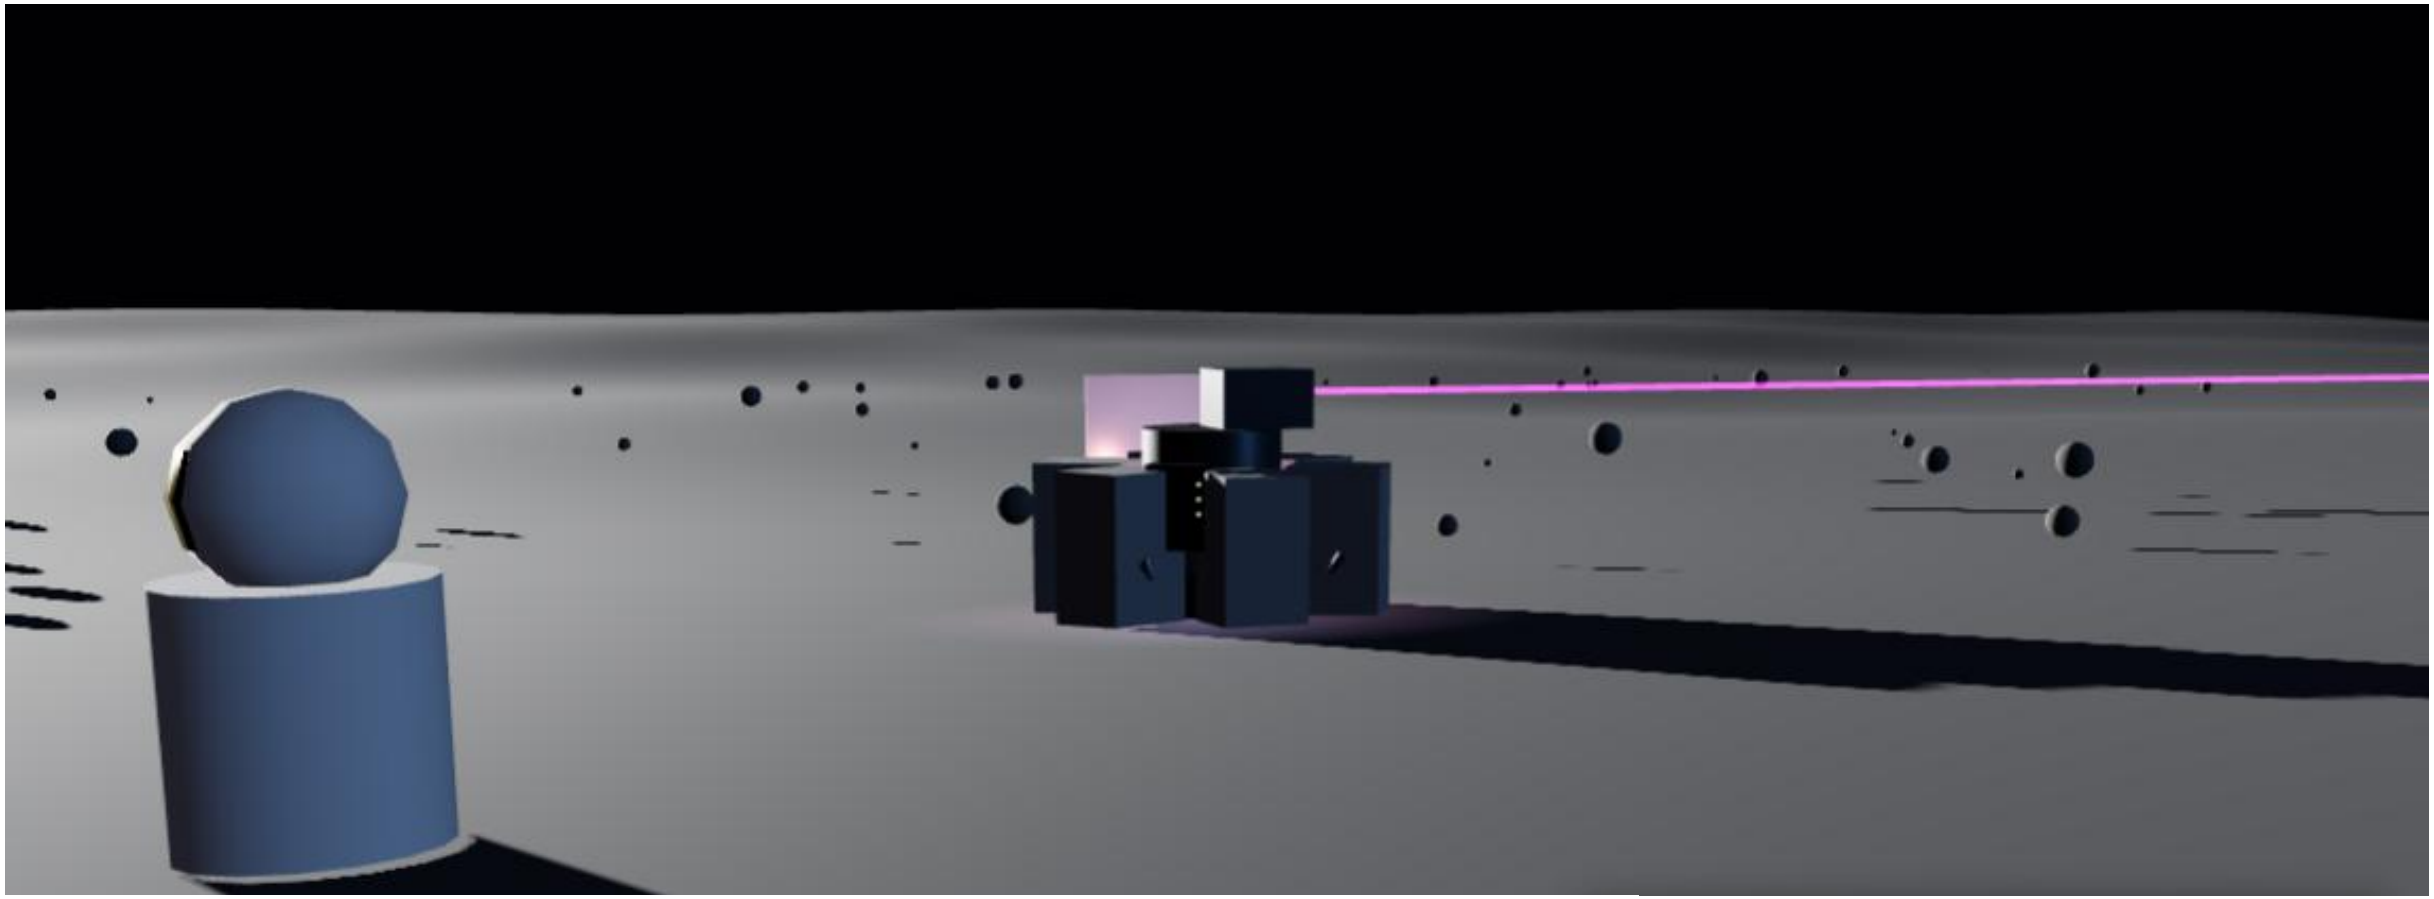
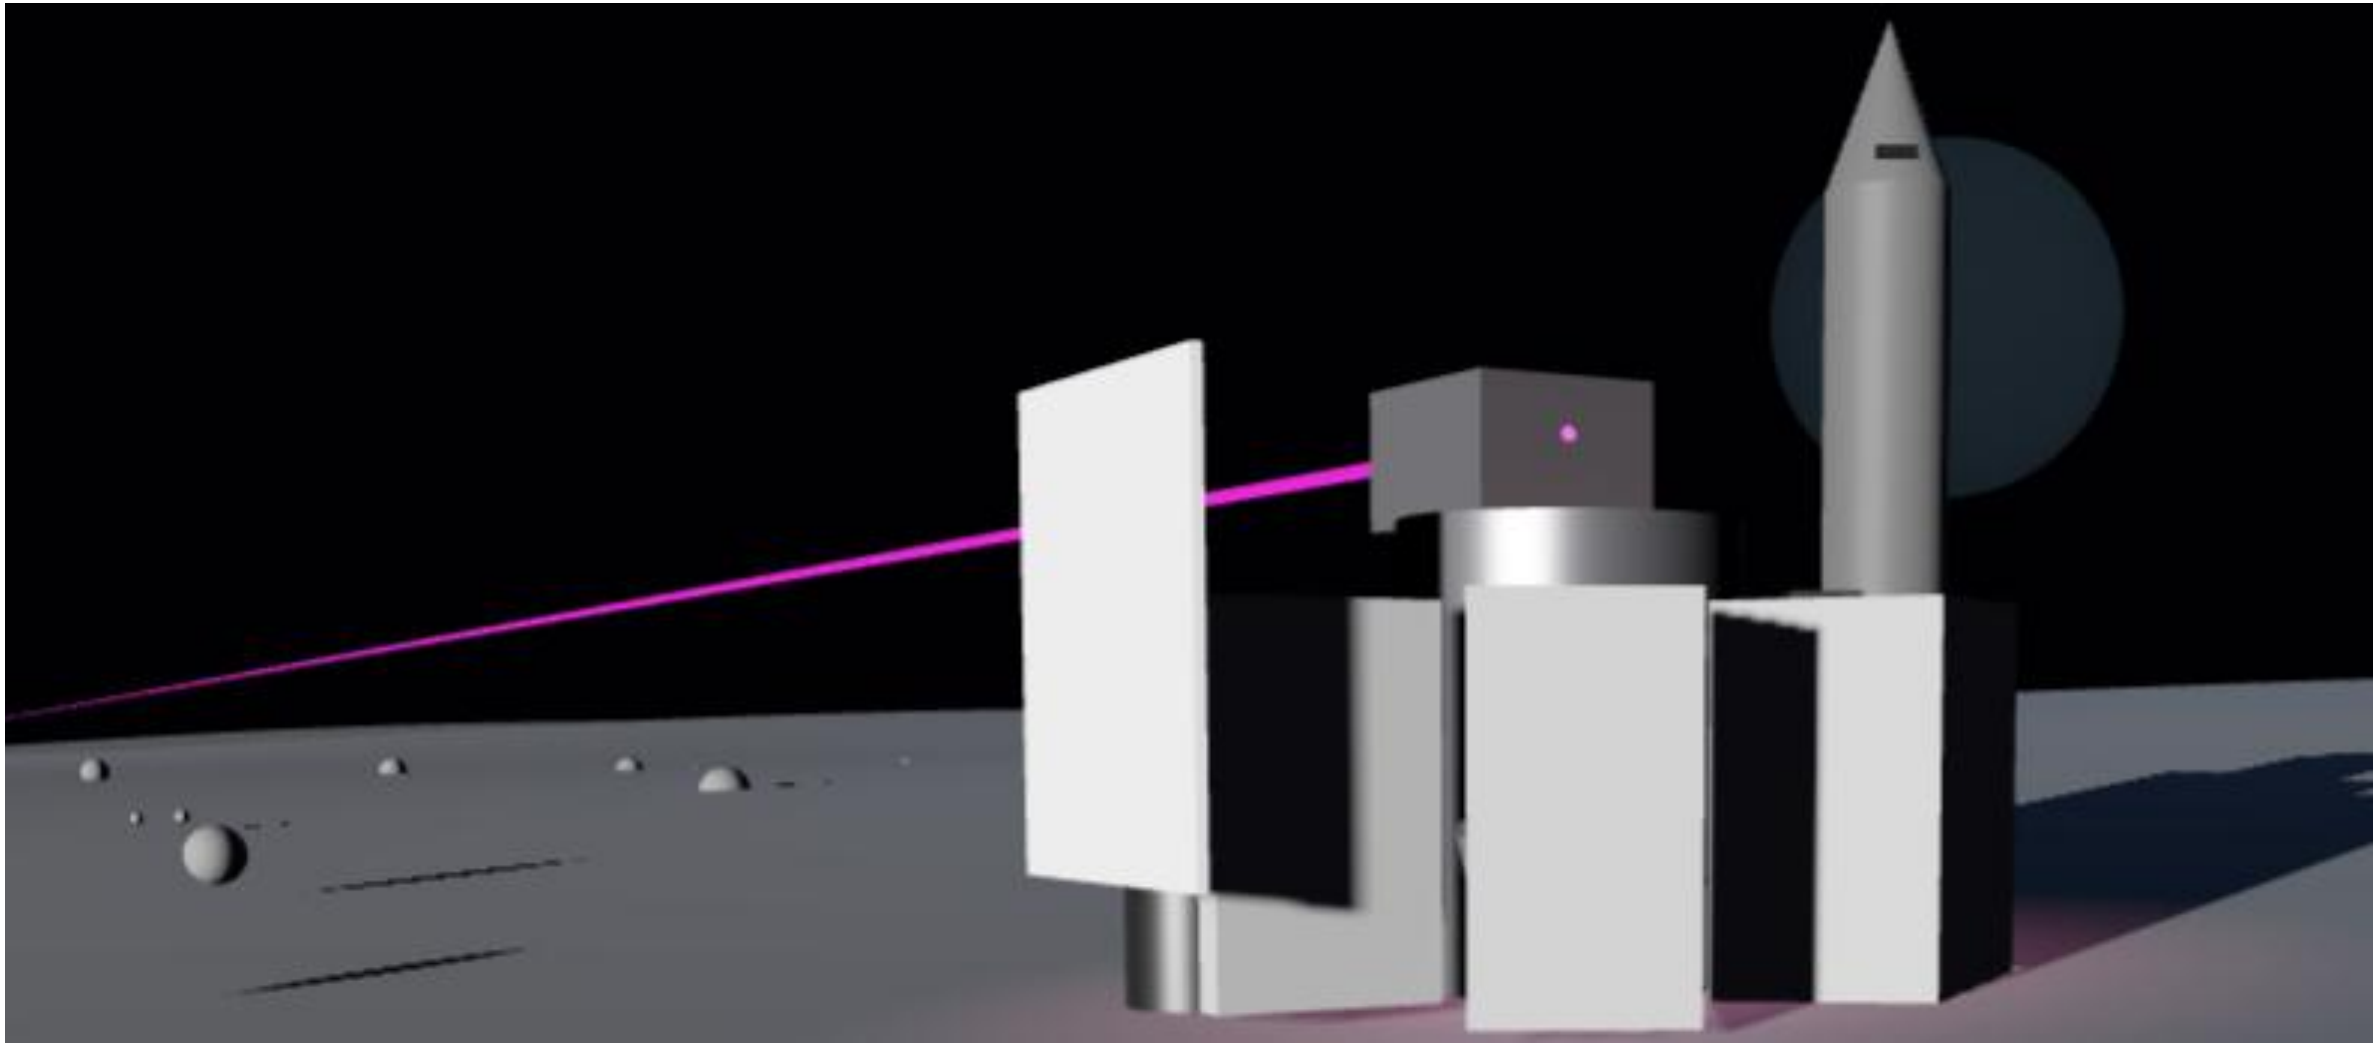


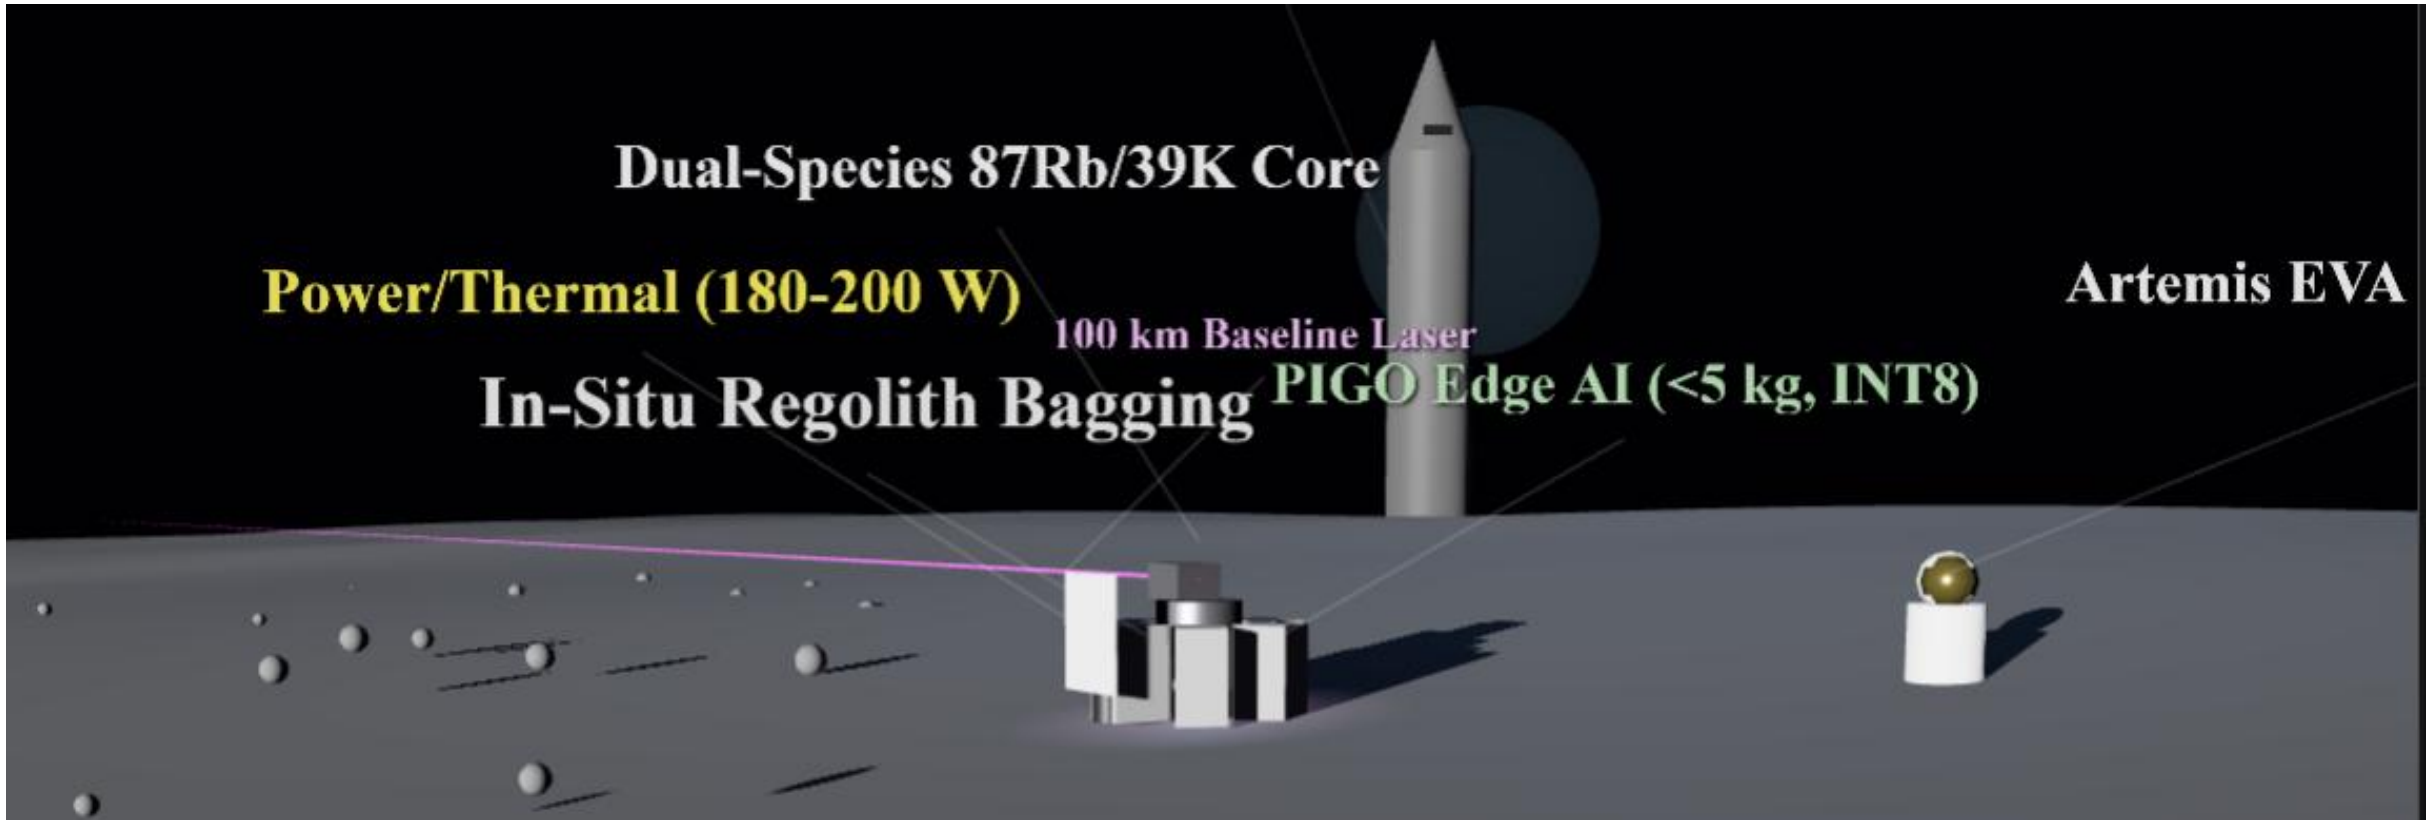
150 kg modular quantum-sensor payload concept labelled



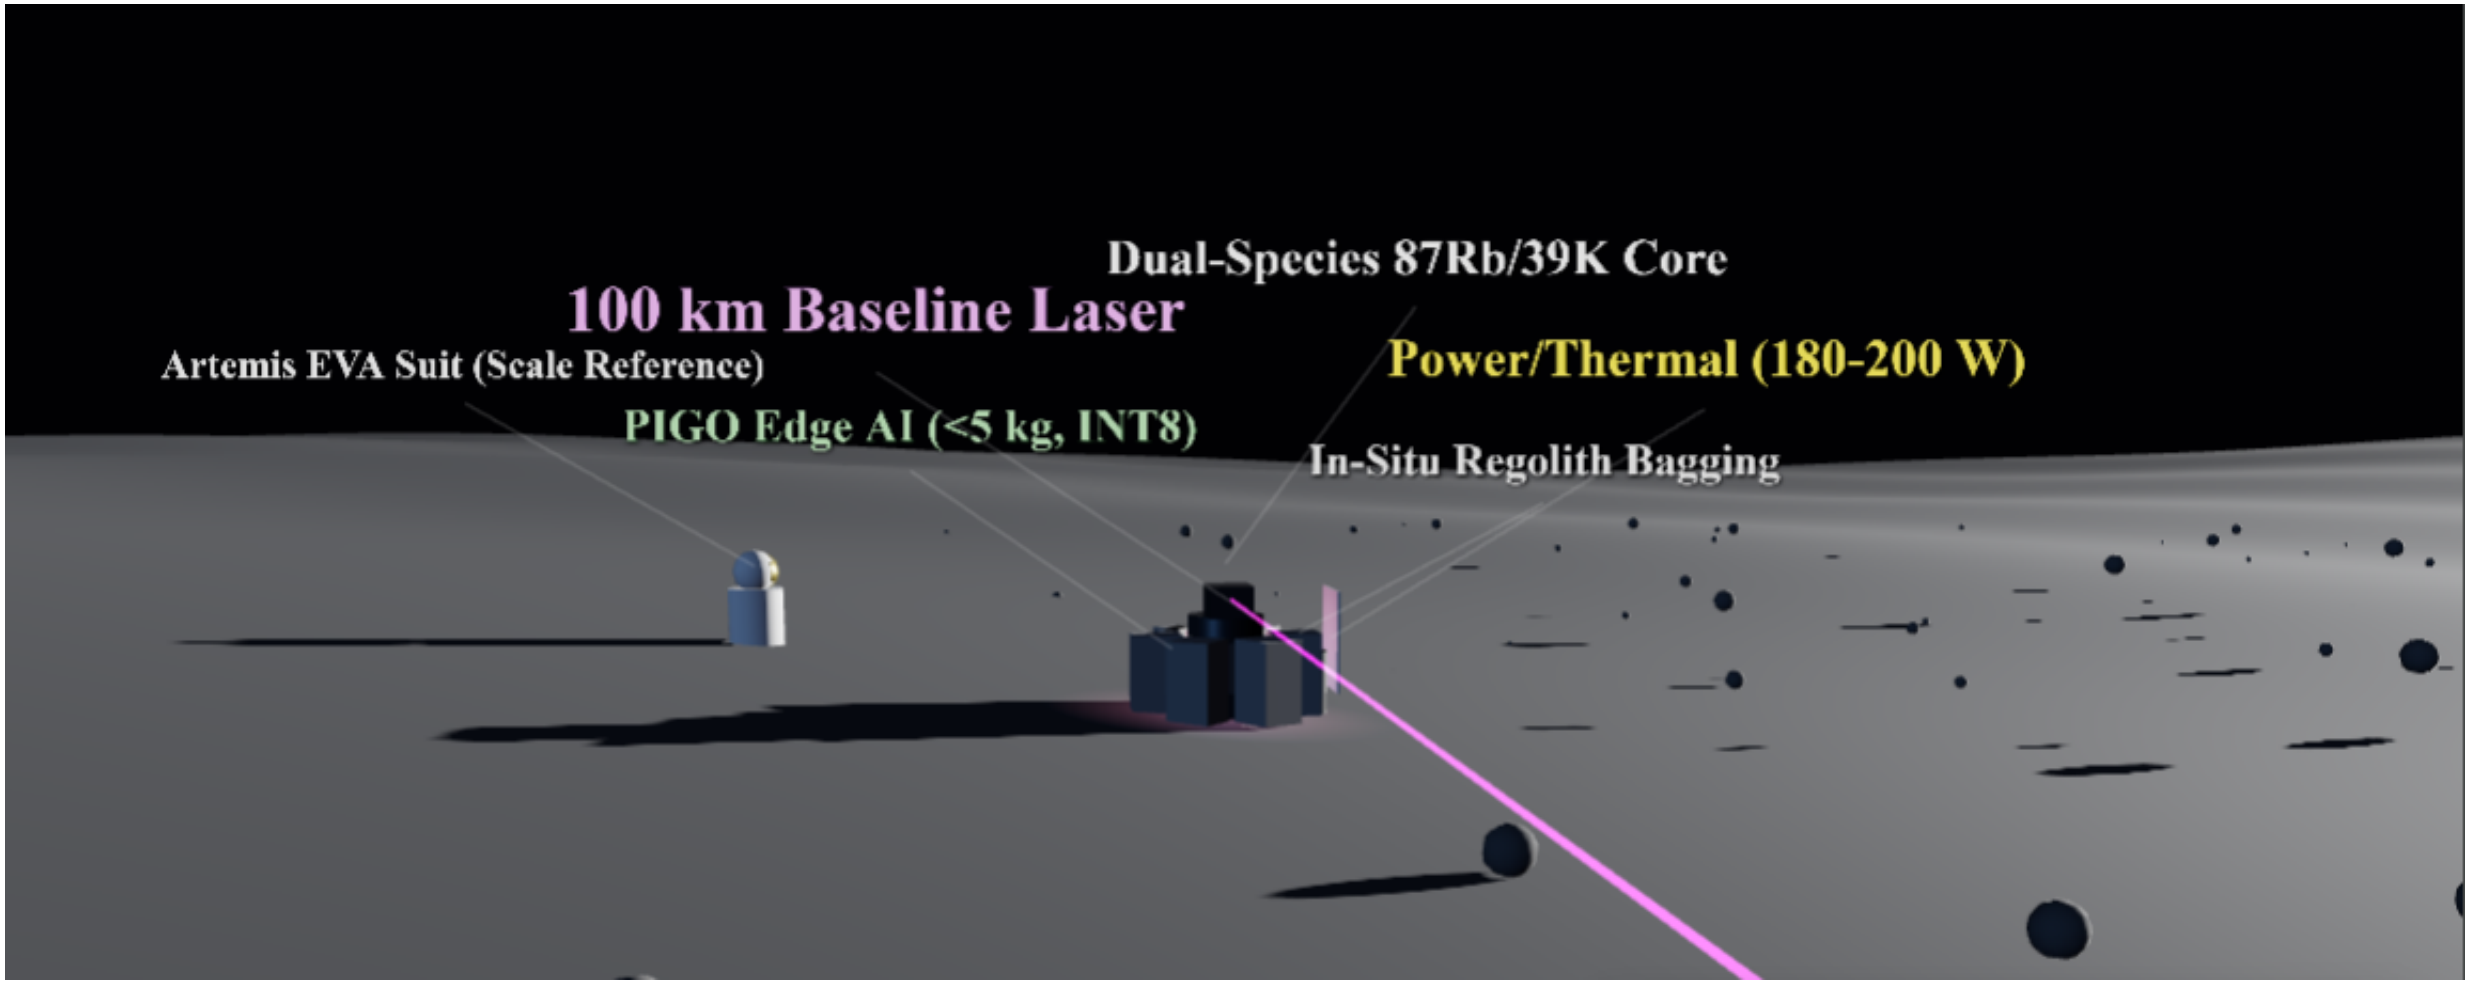
150 kg modular quantum-sensor payload, with human astronaut (Artemis EVA suit) at the lunar South Pole



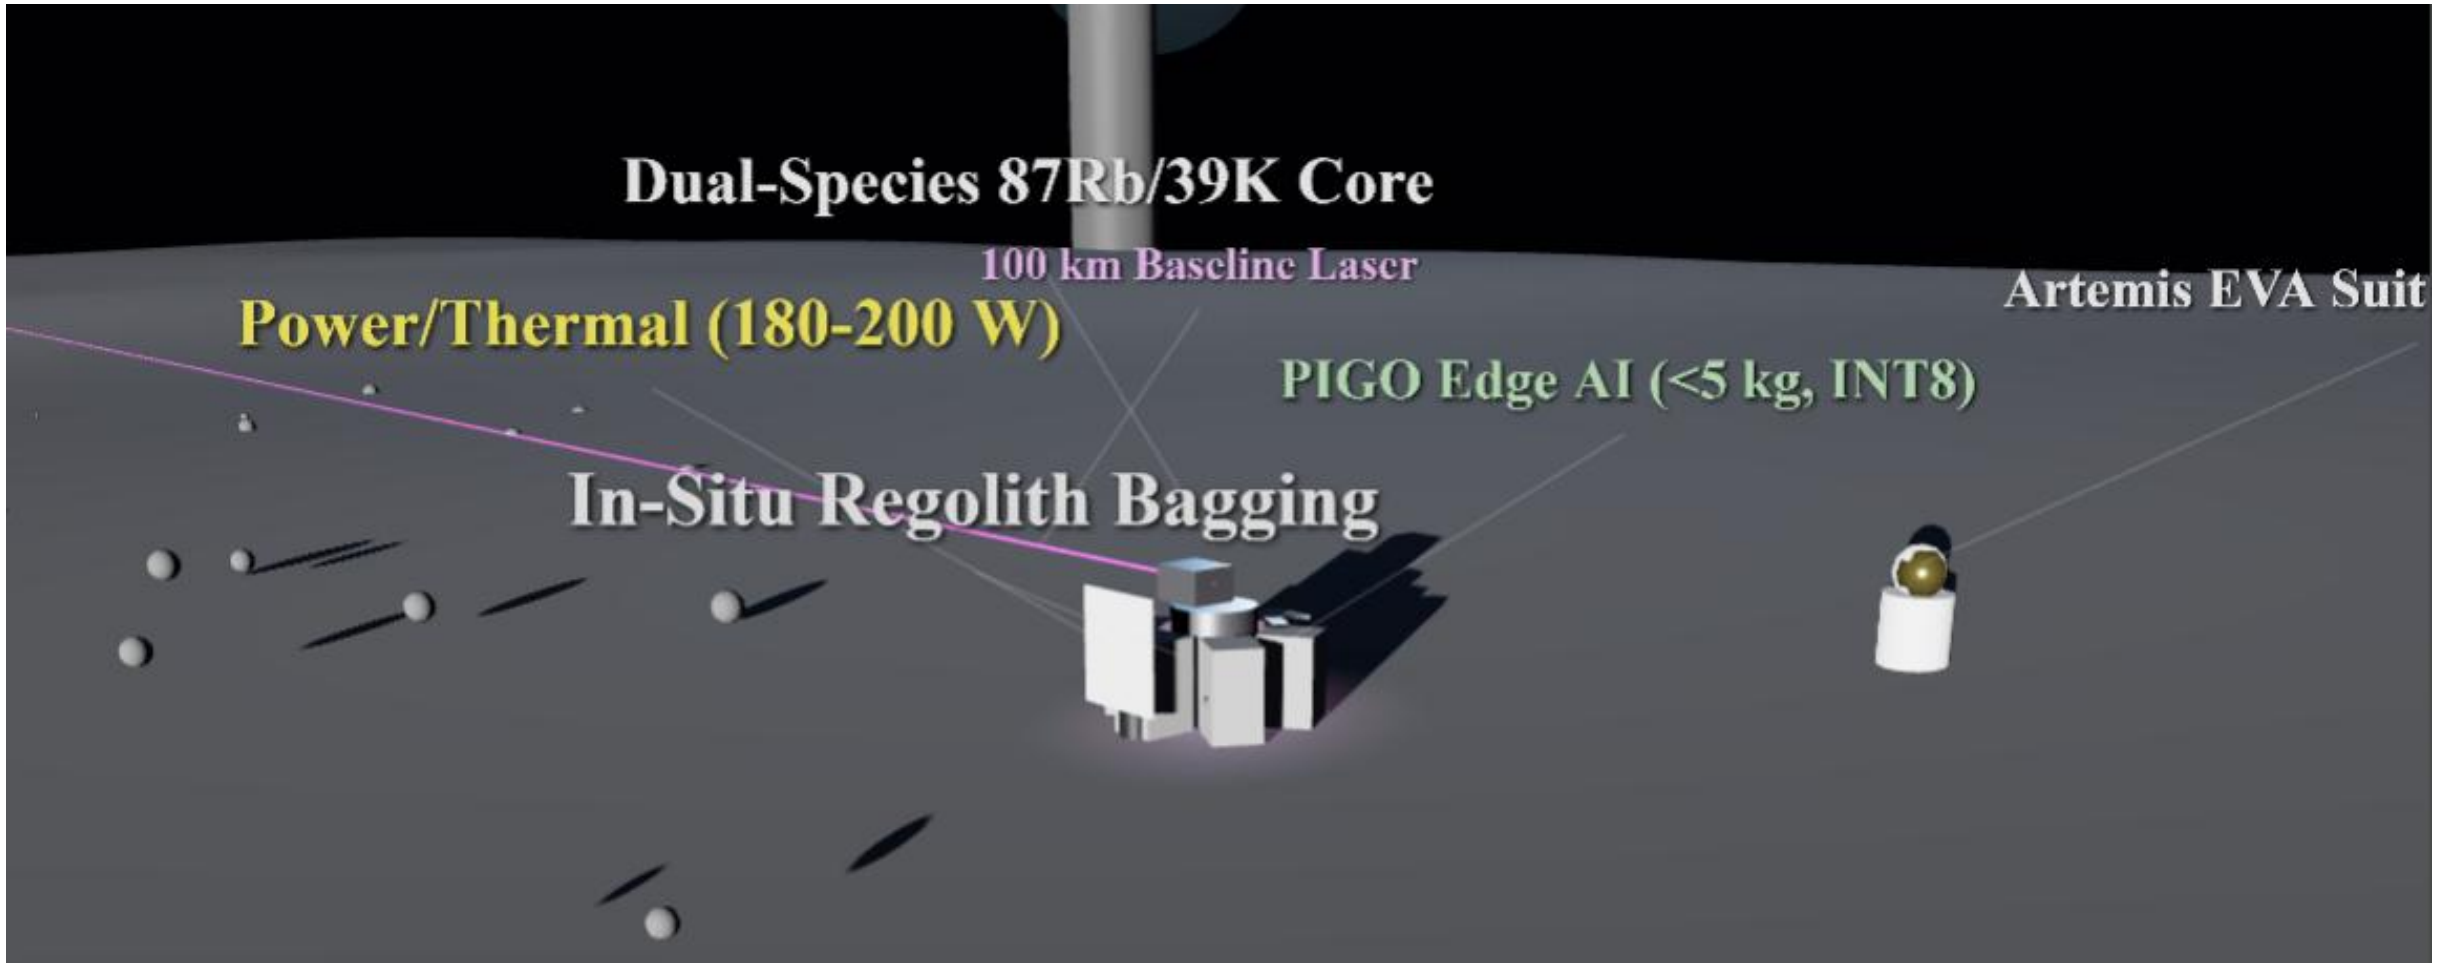
150 kg modular quantum-sensor payload at the lunar South Pole with Artemis IV and Earth



Wide-angle scene overview of the fully deployed 150 kg modular quantum-sensor payload at the lunar South Pole. The hexagonal cluster shares the surface with a Starship HLS (commercial multiplier, visible ~200 m away) serving as a localised logistics hub, with a human astronaut (Artemis EVA suit) standing 5 m away providing scale and faint Earthrise visible on the horizon.



Cutaway view of the Central Core detailing the ^{87}Rb and ^{39}K Magneto-Optical Traps (MOTs). Faint purple laser lines designate the origin of the 100 km baseline.



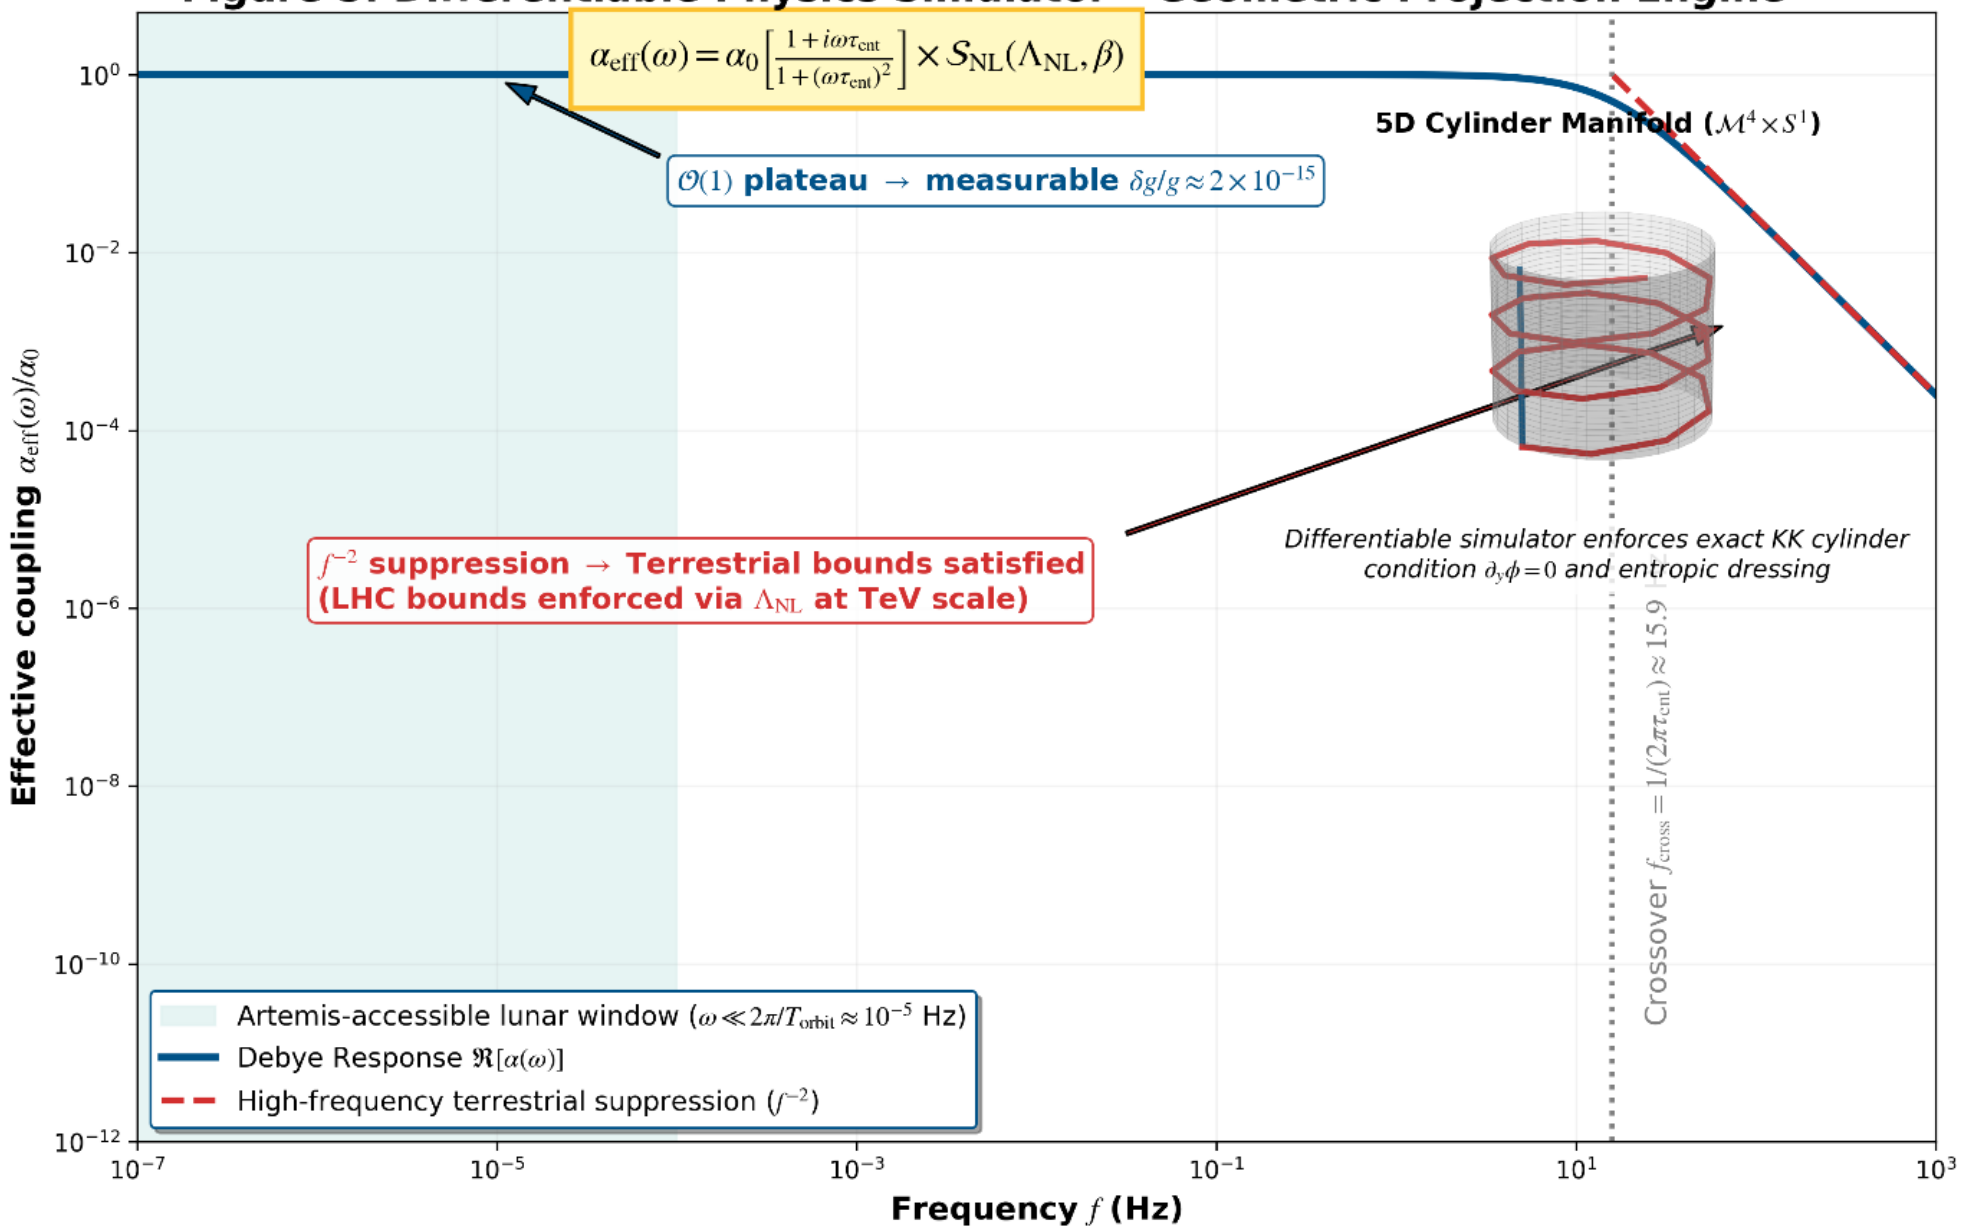
Close-up of the PIGO Edge AI Core and Power Management systems. The AI module enforces physical constraints locally while surviving communication blackouts via the Airlock Protocol; adjacent RTG-style generators and finned radiators manage the 180–200 W power envelope.

NASA's Artemis III: First Human Mission to the Lunar South Pole.

Table 3: Summary of Operational Parameters

Parameter	Value	Description
Compactification Radius (R_5)	10^{-4} m	Defines the scale of the 5D manifold
Entropic Relaxation Time (τ_{ent})	10^{-2} s	Controls holographic frequency response
Non-linear Suppression Power (β)	2.0	Suppresses high-energy modes
Non-linear Cutoff Scale (Λ_{NL})	1 TeV	Collider constraint threshold
Operational Power Envelope	180-200 W	Strict limit for lunar South Pole hardware

Figure 5: Differentiable Physics Simulator – Geometric Projection Engine



Benchmark parameters: $R_5 = 10^{-4}$ m, $\tau_{\rm ent} = 10^{-2}$ s, $\Lambda_{\rm NL} = 1$ TeV.
Output: Clean, geometrically valid phase-shift spectrum $\delta\phi \sim 10^{-12}$ rad at 100 km baseline.

Figure 6: **PIGO End-to-End Edge Architecture.** High-bandwidth raw telemetry (> 1 Mbps) is filtered at the Lunar Gateway edge using Medallion-layer compute. Actionable Gold tensors ($\mathbb{R}^{B\times T\times 2}$) are then relayed via the 10 kbps Deep Space Network (DSN) bottleneck, enabling real-time signal isolation and AI phase-shift recovery.

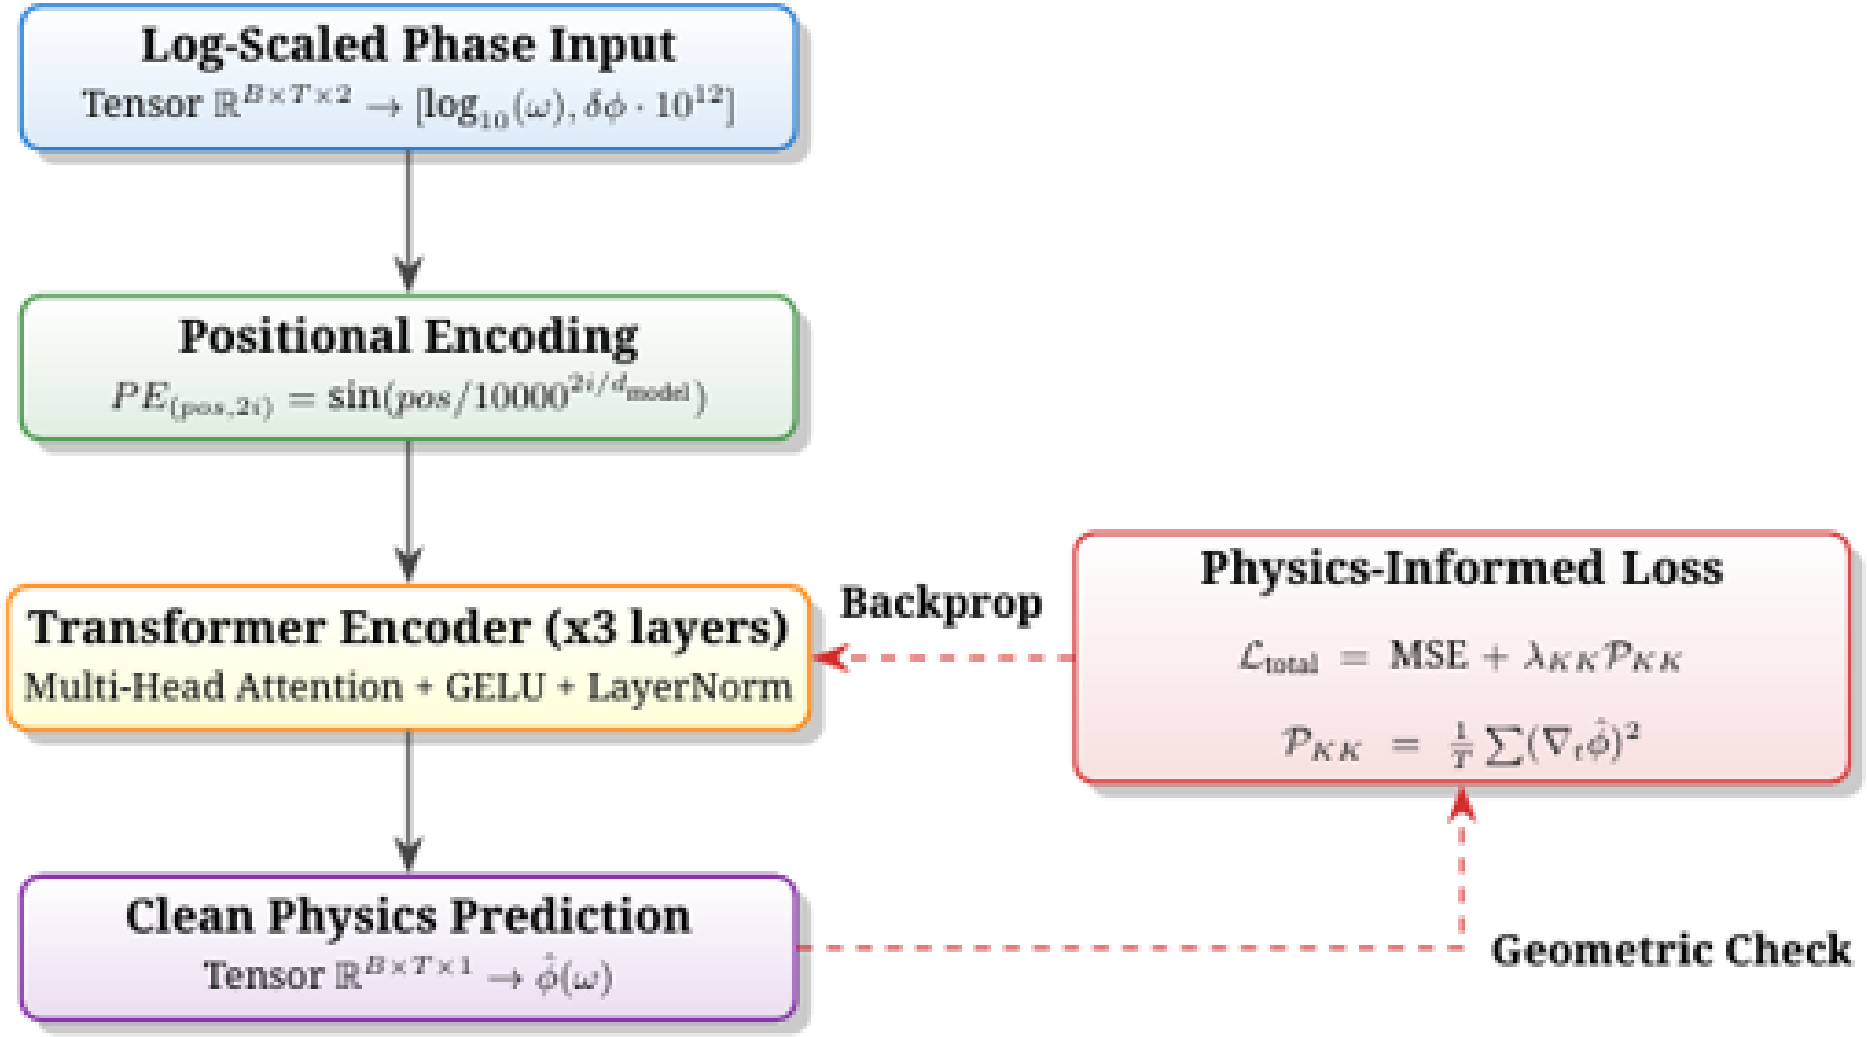


Figure 7: **Physics-Informed Transformer (PIT) Architecture.** Neural core utilizing a 10^{12} precision scale factor to bypass 'float32' gradient underflow in the sub-atomic phase regime. The custom loss function enforces a derivative penalty ($\mathcal{P}_{KK}$) to algorithmically guarantee geometric flatness of the prediction, strictly prohibiting non-physical resonance spikes.

Box 2: Phase 0 Pathfinder — Immediate Re-Analysis of Public Artemis II Data

Objective: The low-cost first step is re-analysis of public Artemis II telemetry to calibrate the PIT/PIGO pipeline and obtain preliminary constraints on $\alpha_{eff}(\omega)$.

Public Data Sources: NASA Artemis Realtime Orbit Website (AROW) ephemeris and state vectors; public radiation dosimetry and inertial measurement unit (IMU) residuals from the Artemis II data release (NASA SP-2026-001 and Planetary Data System).

3-Step Protocol: (1) Download trajectory and microgravity data; (2) perform frequency-domain search for residuals in the ultra-low-ω window ($\omega \ll 2\pi/T_{orbit}$); (3) apply PIGO boundary enforcement to isolate screened-dilaton signatures.

Open Science: All derived PIGO models and Phase 0 results will be open-sourced under a NASA-compatible licence to enable global collaboration and citizen-science extensions.

Strategic Gate: This Phase 0 analysis provides the first calibrated observational constraints on the screened dilaton coupling and serves as the formal 'Go/No-Go' gate for full surface deployment on Artemis III.

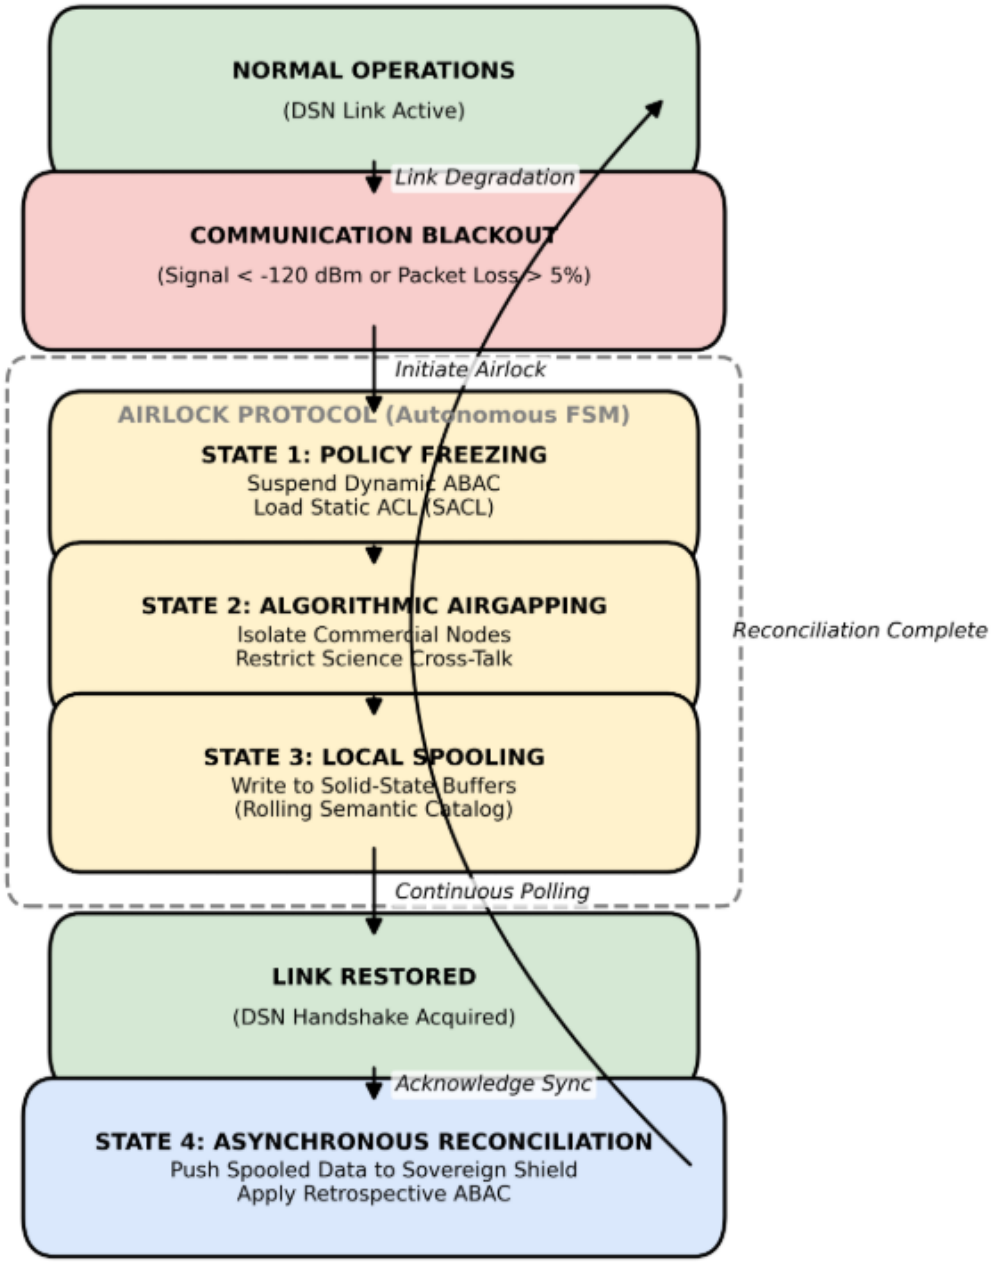

Figure D.3a: **Airlock Protocol – Deterministic Finite-State Machine** The Airlock Protocol is implemented as a deterministic finite-state machine. The diagram shows the transition from Normal Operations through Policy Freezing, Algorithmic Airgapping, and Local Spooling, to Asynchronous Reconciliation upon link restoration.

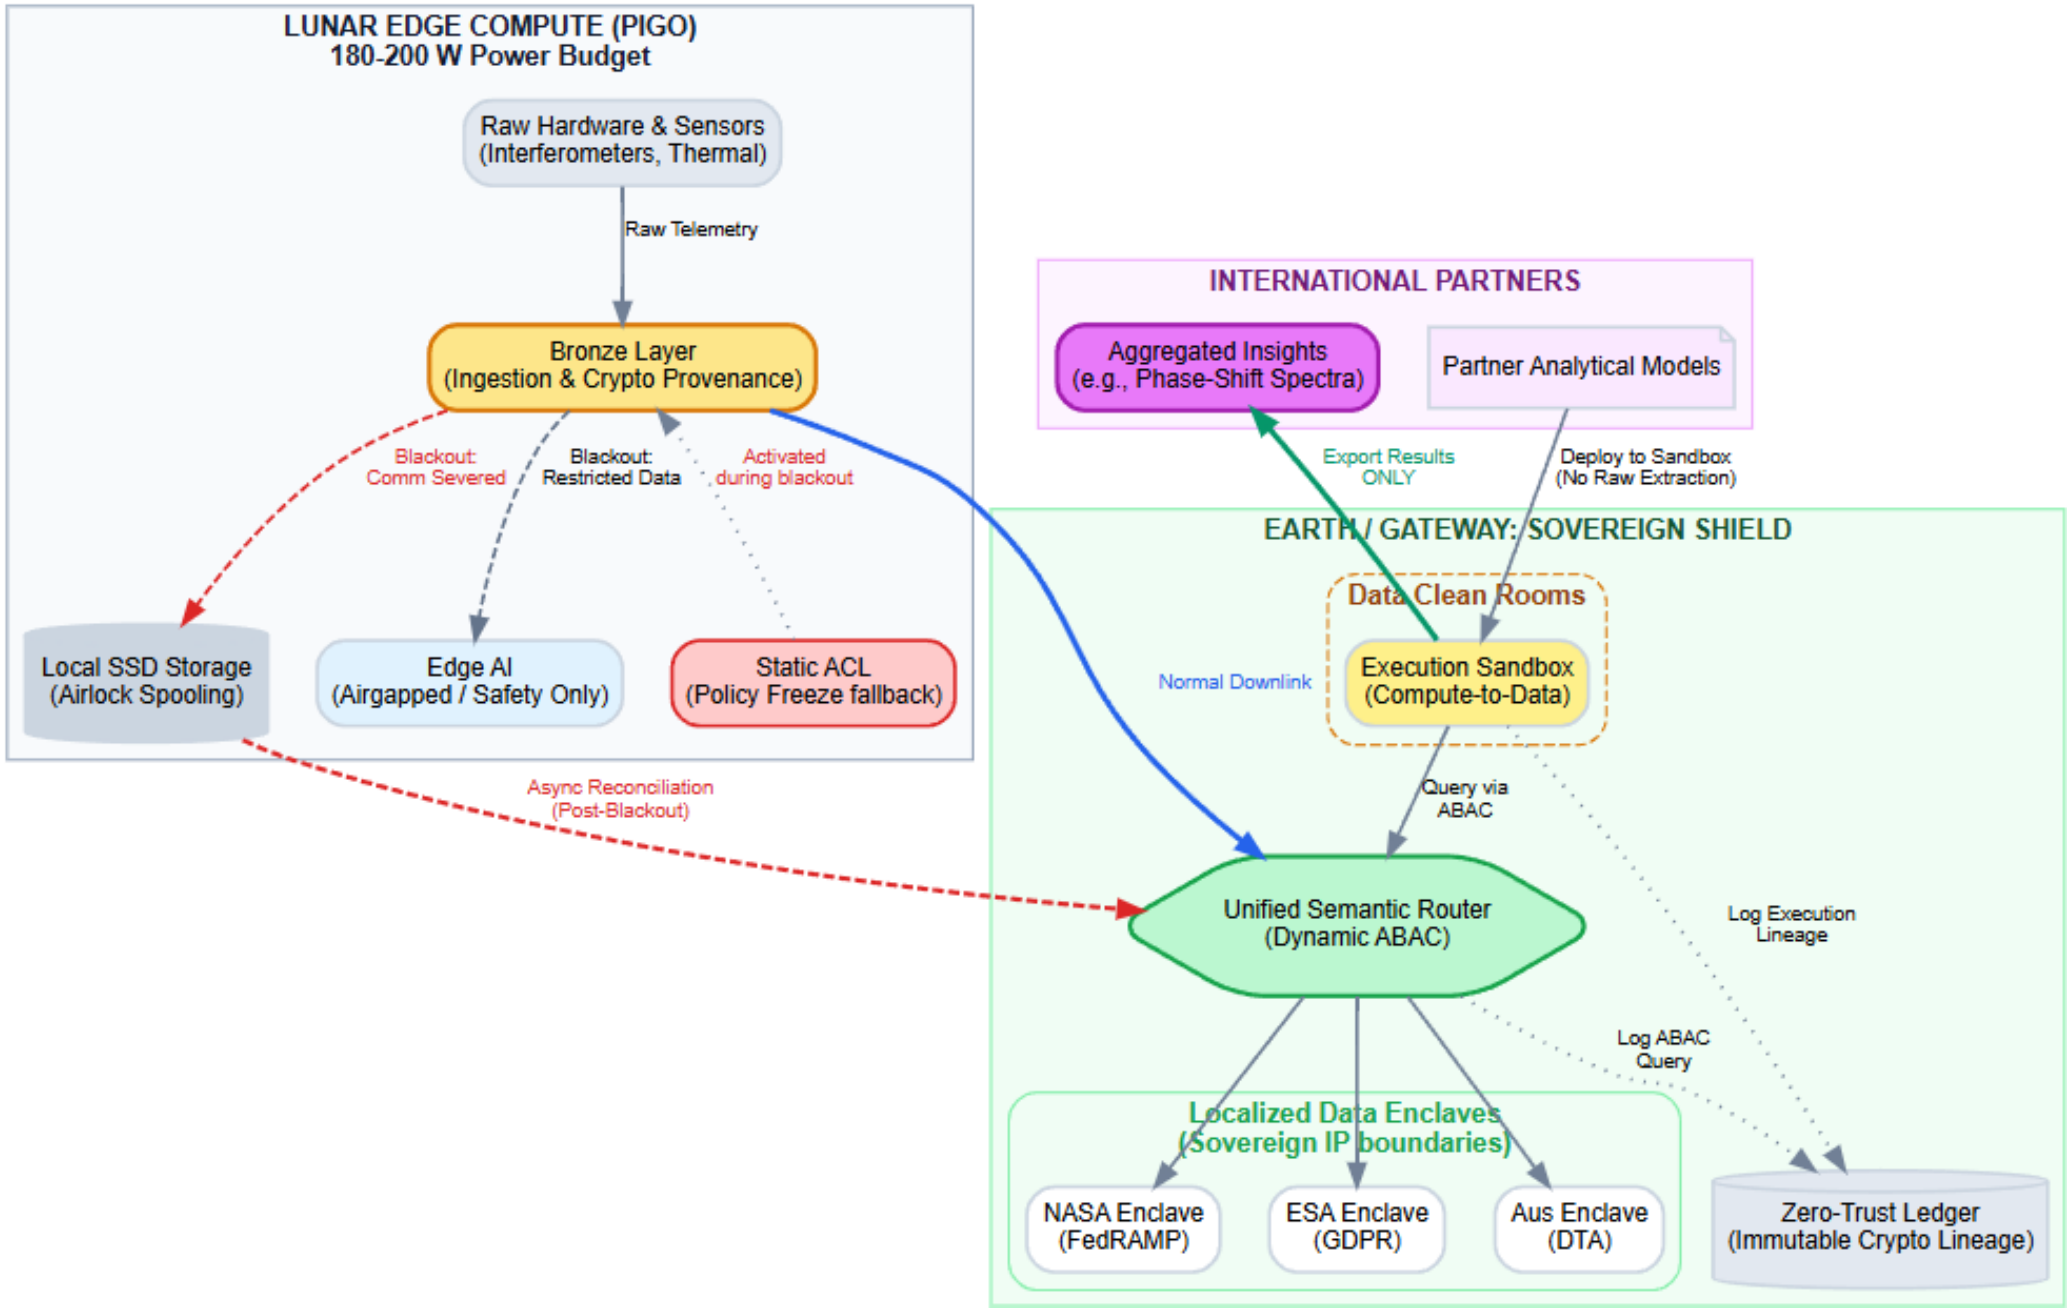

Figure D.3b: **Sovereign Data Governance and Edge-Compute Resilience, Structuring Intellectual Property and Data Firewalls**

Figure E.1: Phase 0 Pathfinder Signal Verification

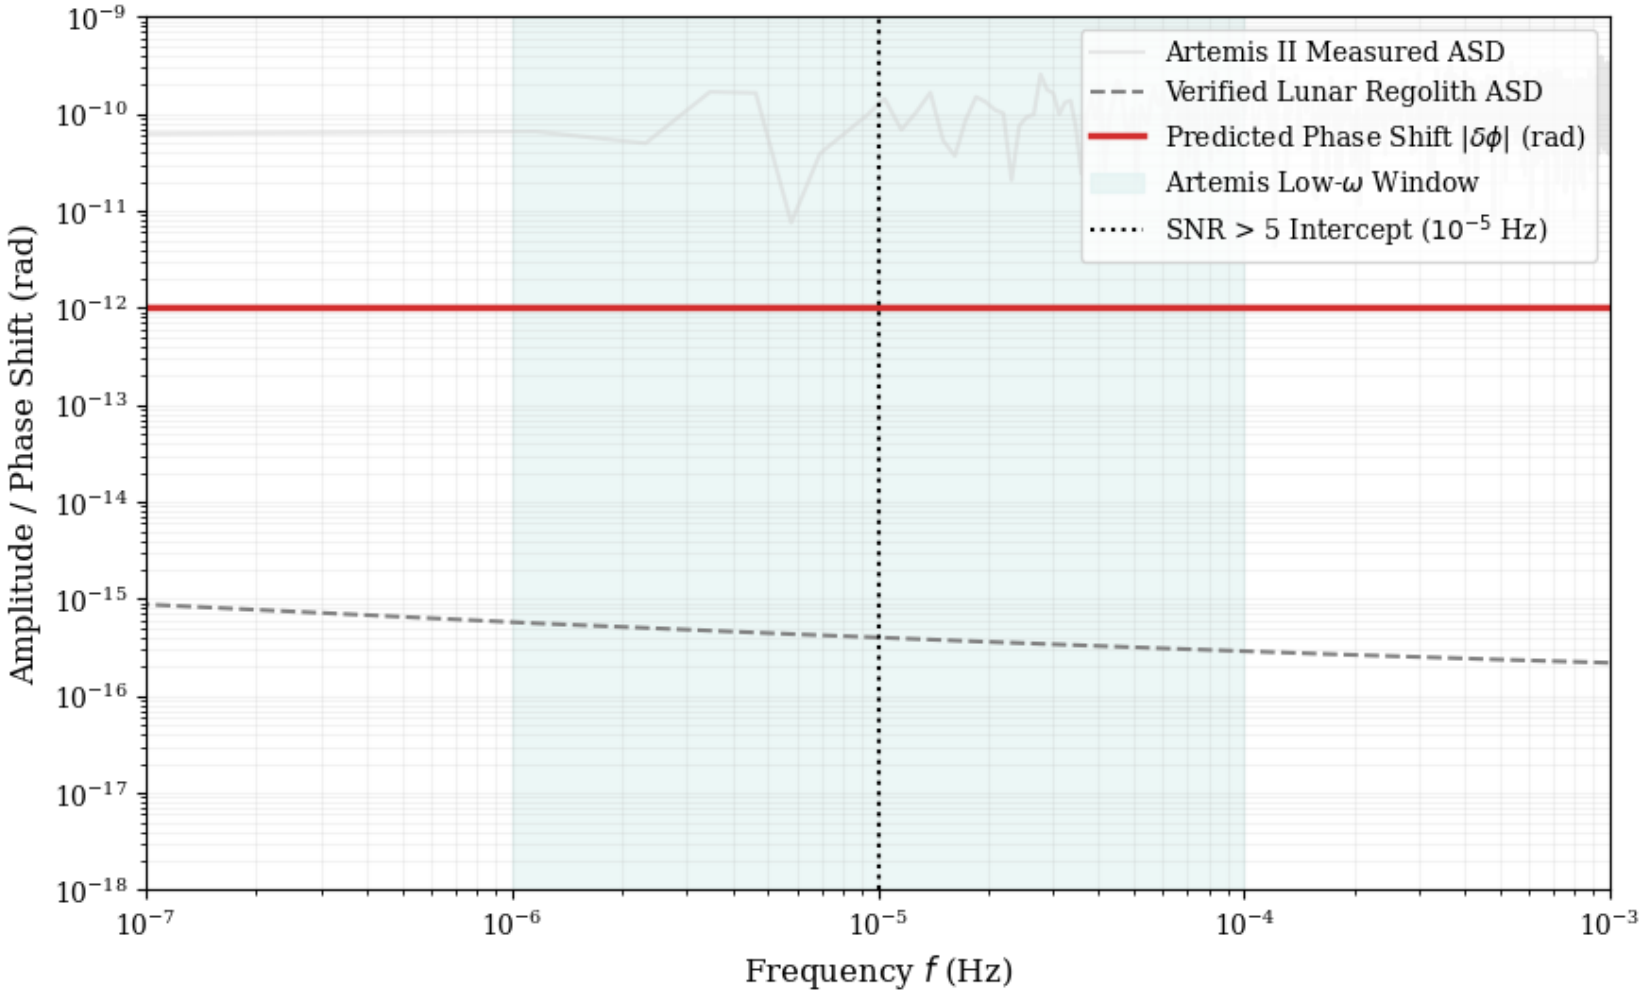

Figure E.1**: Preliminary Phase 0 validation.** Black: measured Orion acceleration ASD from Artemis II free-fall segments. Red dashed: predicted signal plateau ($\delta g/g \approx 2 \times 10^{-15}$). Blue: lunar ASD model (Appendix F). The Artemis-accessible window ($\omega \ll 2\pi/T_{\text{orbit}}$) is shaded. The analysis confirms noise suppression > 95 % and places the first in-situ constraint on the screened dilaton coupling.

The Artemis II flyby data (light grey) confirm our detailed understanding of the deep-space noise environment. The predicted target signal (red) remains too faint to detect from orbit, but landing the Rocky payload on the ultra-quiet lunar surface (dashed grey) mathematically clears the Phase 0 'Go/No-Go' threshold for a 5σ detection of emergent 5D gravity.

Table 4: SWaP-C Optimised Modular Payload Concept

Module	Mass	Power	Primary Function	TRL	Strategic Advantage
Dual-Species Atom Interferometer Core (^{87}Rb+^{39}K)	80 kg	120 W	Differential WEP testing & gravity sensing	6-7	Common-mode noise cancellation
PIGO Edge Compute Unit	$\leq$ 5 kg	$\leq$ 20 W	Real-time 5D geometric projection	5	Low-power, rad-hardened edge AI
Regolith-Based Thermal Shielding	0 kg (in-situ)	0 W	Passive thermal stability ($\pm 120^{\circ}$C)	8	Mass reduction via ISRU
Supporting Clocks & Gradiometers	40-80 kg	40-60 W	Precision timing & gradient mapping	6	Modular plug-and-play
Total Suite	50-200 kg	180-200 W	Full quantum-sensor + AI co-pilot suite	-	Compatible with Starship HLS & Lunar Gateway

Table 5: Strategic Technical Benchmarks

Parameter	Value	Description
Compactification Radius (R_5)	10^{-4} m	Defines the scale of the 5D manifold
Entropic Relaxation Time (τ_{ent})	10^{-2} s	Controls holographic frequency response
Non-linear Suppression Power (β)	2.0	Suppresses high-energy modes
Operational Power Envelope	180-200 W	Strict limit for lunar South Pole hardware

Table G.1 Fully Deployed 150kg Modular Quantum-Sensor Payload (Rocky)

FULLY DEPLOYED 150 kg MODULAR QUANTUM-SENSOR PAYLOAD

Location: Lunar South Pole near Shackleton Crater rim (permanently sunlit ridge, April 2028 Artemis IV-era).

Atmosphere and Lighting: Harsh lunar daylight, high contrast, deep black sky. Sun is low on horizon, casting long shadows.

Background Context: Distant crater rim, faint Earthrise (tiny blue-white marble).

Scale Indicators: Human astronaut (Artemis EVA suit) standing 5 m away. Starship HLS visible 200 m away.

CENTRAL CORE (Atom Interferometer)

- 0.8 m tall, 0.6 m diameter
- Polished titanium vacuum chamber
- Red / Blue glowing MOTs & Optical Lattices
- Counter-propagating Lasers (1064 nm & 780 nm)

REGOLITH BAGGING SYSTEM

- High-strength polyimide bags
- 15–20 cm thick in-situ lunar regolith
- Textured outer layer with Copper Mesh
- Electrostatic dust-repellent grids

KEY ANNOTATIONS

- Dual-species ^{87}Rb / ^{39}K Atom Interferometer – 100 km baseline
- Regolith bagging: passive thermal/ radiation shield (±120 °C, TRL 6–7)
- PIGO Edge AI Core (<5 kg) – enforces 5D KK + entropic boundaries
- Power envelope: 180–200 W (Starship HLS / CLPS compatible)
- Benchmark parameters: $R_5 = 10^{-4}$ m, $\tau_{ent} = 10^{-2}$ s, $\beta = 2.0$
- Predicted signal: $\delta g/g \approx 2 \times 10^{-15}$, SNR > 5 (Artemis window)
- **Airlock Protocol active during comms blackouts**

PIGO EDGE AI CORE

- Compact black rectangular box (<5 kg)
- Rad-hardened INT8/FP4 inference chips
- Running 4-layer Medallion pipeline
- Status: [•] Green LEDs - Airlock Active

POWER & THERMAL

- Two RTG-style generators (or Solar/Battery)
- 180–200 W continuous power draw
- White, finned heat radiators extending from bags

LASER & OPTICAL BENCH

- 30 kg separate module
- Fibre-coupled lasers & beam directors
- Pointing toward 10–20 km fallback / Gateway

DEPLOYMENT STATE

- 4 low-profile landing legs with regolith anchors
- Connected by dust-sealed umbilicals
- Small rover arm adding final regolith bag (ISRU)

ATOM SOURCE

Close-up showing dual-species MOTs and optical lattice. Red/Blue glowing trap dynamics.

PIGO PIPELINE

1. Bronze Layer (Ingest) | 2. Silver Layer
3. Gold Layer | 4. Differentiable Physics Sim

FREQUENCY PLOT

Plot of $\alpha_{eff}(\omega)$ showing the lunar window ($\omega \ll 2\pi/T_{orbit}$) where the screened signal appears.

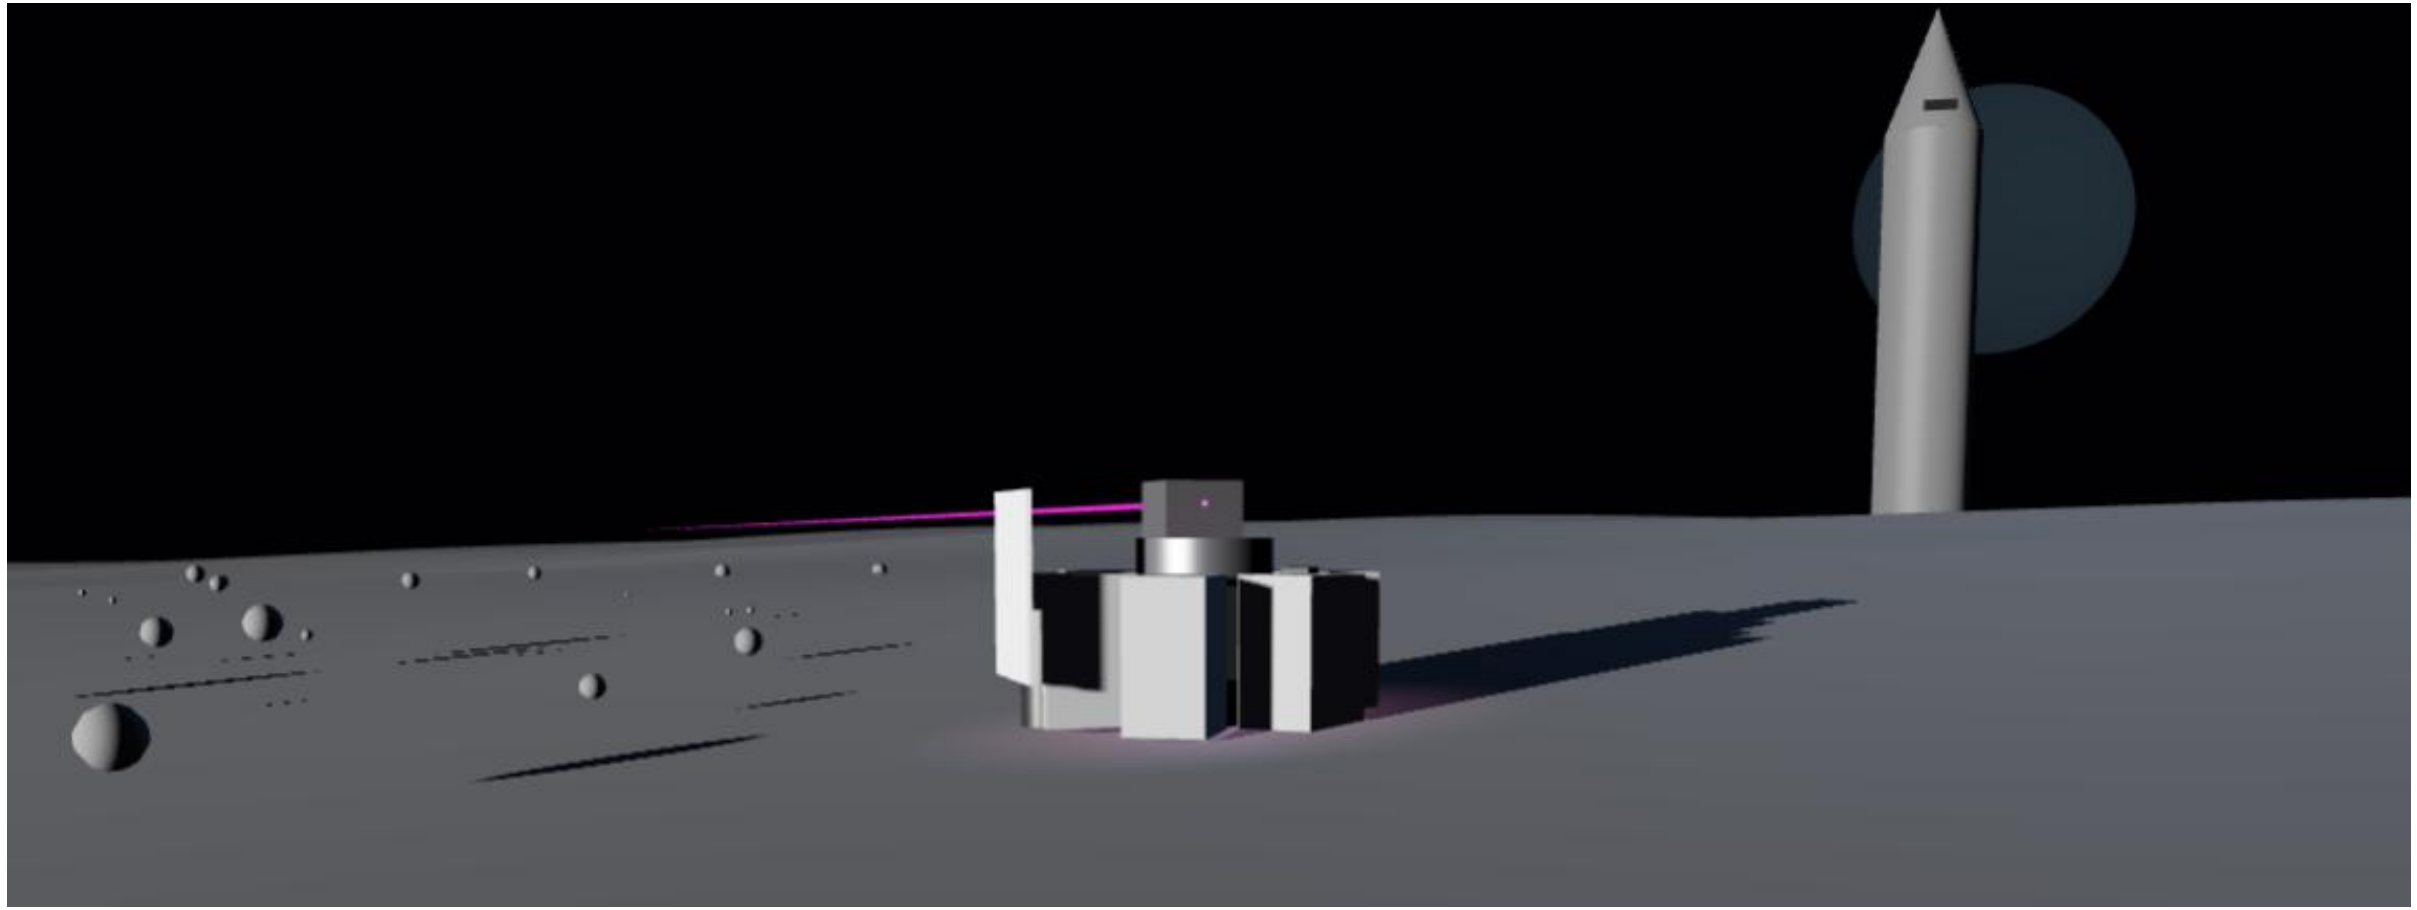
BUILDABILITY CERTAINTY: 100% WITH 2026 TECHNOLOGY

All core components are at TRL 5–7 with direct heritage from CAL/BECCAL, MAGIS-100, and CLPS missions.

The 100 km configuration requires only integration and lunar qualification — no new physics or exotic materials.

Table G.2: Risk Mitigation for Rocky Payload (Excerpt)

Risk Category	Specific Risk	Likelihood (1–5)	Severity (1–5)	Current Controls	Residual Risk	Mitigation Timeline
Technical	Regolith vibration / thermal cycling	3	4	Passive regolith bagging + VCHPs + PCM	Low	Ground TVAC testing (2026–2027)
Technical	Dust contamination of optics	4	4	EDS + gas-curtain system + copper mesh	Low	Phase 0 dust-mitigation demo (2027)
Technical	Power budget overrun	2	3	Power-throttling + INT8/FP4 quantization	Very Low	Real-time monitoring in Phase 0
Programmatic	Launch window slip	3	3	Modular "plug-and-play" design	Low	CLPS/Starship HLS compatibility (2027)
Safety	Communication blackout	4	4	Airlock Protocol (deterministic FSM)	Low	Full simulation in Phase 0
Safety	Crew command conflict	2	5	Three-stage guardrails + crew override	Very Low	Astronaut training integration



Fully Deployed ROCKY Payload at the Lunar South Pole. Wide-angle view of the 150 kg modular quantum-sensor payload in its operational configuration near Shackleton Crater. The dual-species $^{87}Rb/^{39}K$atom interferometer core (centre) is thermally stabilised by in-situ regolith bagging. The 100 km laser baseline is shown in magenta, with the PIGO Edge AI unit and power/thermal radiators clearly visible. A Starship HLS lander (~200 m distant) serves as a logistics hub, while an Artemis EVA astronaut provides human scale. This configuration achieves the required 180–200 W power envelope and SNR > 5 for the predicted $\delta g/g \approx 2 \times 10^{-15}$signal.

Appendix I: List of Symbols

Symbol	Definition	Benchmark Value
R_5	Compactification radius of the 5th dimension	10^{-4} m
τ_{ent}	Entropic relaxation time (holographic island scale)	$\approx 10^{-2}$ s
β	Non-linear suppression power	2.0
Λ_{NL}	Non-linear cutoff scale	1 TeV
$\alpha(\omega)$	Frequency-dependent screening function	$\alpha_0 \frac{1+i\omega\tau_{ent}}{1+(\omega/\omega_{cross})^{2\beta}}$
$\delta g/g$	Predicted fractional gravitational deviation	$\approx 2\times 10^{-15}$
$\delta\phi$	Phase shift in atom interferometer	$\sim 10^{-12}$ rad (100 km baseline)
SNR	Signal-to-noise ratio	>5 (target)
